COVID-19 Results Briefing

Bangladesh

May 27, 2021

This document contains summary information on the latest projections from the IHME model on COVID-19 in Bangladesh. The model was run on May 26, 2021 with data through May 24, 2021.

Current situation

- Daily reported cases in the last week decreased to 1,000 per day on average compared to 1,200 the week before (Figure 1).
- Daily deaths in the last week decreased to 130 per day on average compared to 130 the week before (Figure 2). Estimated total daily COVID-19 deaths were 4.1 times larger than the reported number of deaths. This makes COVID-19 the number 4 cause of death in Bangladesh this week (Table 1).
- The daily death rate is greater than 4 per million in India, Maldives, Nepal, and Sri Lanka (Figure 3).
- We estimated that 38% of people in Bangladesh have been infected as of May 24 (Figure 5).
- Effective R, computed using cases, hospitalizations, and deaths, is greater than 1 in 9 countries (Figure 6). The Effective R in Bangladesh on May 13 was 1.06.
- The infection detection rate in Bangladesh is close to 1% on May 24 (Figure 7).
- In Bangladesh we estimate that the primary circulating variants are escape variants (B.1.351, B.1.617, or P.1). We estimate that B.1.351 is circulating in 7 countries, that B.1.617 is circulating in 5 countries, and that P.1 or P.3 is circulating in 3 countries.

Trends in drivers of transmission

- Mobility last week was 11% lower than the pre-COVID-19 baseline (Figure 10). Mobility was near baseline (within 10%) in no countries. Mobility was lower than 30% of baseline in India, Maldives, Myanmar, Nepal, Sri Lanka, Thailand, and Timor-Leste.
- As of May 24 we estimated that 65% of people always wore a mask when leaving their home compared to 66% last week (Figure 12). Mask use was lower than 50% in Timor-Leste.
- There were 8 diagnostic tests per 100,000 people on May 24 (Figure 14).
- In Bangladesh 77.3% of people say they would accept or would probably accept a vaccine for COVID-19. This is up by 0.4 percentage points from last week. The fraction of the population who are open to receiving a COVID-19 vaccine ranges from 59% in Myanmar to 85% in Thailand (Figure 18).
- In our current reference scenario, we expect that 16.63 million people will be vaccinated by September 1 (Figure 19).
Projections

- In our reference scenario, which represents what we think is most likely to happen, our model projects 64,000 cumulative deaths on September 1, 2021. This represents 13,000 additional deaths from May 24 to September 1 (Figure 20). Daily deaths are expected to decline steadily until September 1 (Figure 21).

- If universal mask coverage (95%) were attained in the next week, our model projects 4,500 fewer cumulative deaths compared to the reference scenario on September 1, 2021 (Figure 20).

- Under our worse scenario, our model projects 68,000 cumulative deaths on September 1, 2021, an additional 4,000 deaths compared to our reference scenario (Figure 20).

- By September 1, we project that 500 lives will be saved by the projected vaccine rollout.

- Figure 23 compares our reference scenario forecasts to other publicly archived models. Forecasts are widely divergent.

- At some point from May through September 1, 9 countries will have high or extreme stress on hospital beds (Figure 24). At some point from May through September 1, 9 countries will have high or extreme stress on ICU capacity (Figure 25).
Model updates

We made an update to our vaccine coverage projections this week to better account for the observed scale-up of vaccination. We used data from countries and states with minimal supply constraints (Israel, Chile, Bahrain, states in the United States, locations in the United Kingdom). We used a hierarchical spline model with a monotonicity constraint. Specifically, we model the logit fraction of the population that has been vaccinated among the population that reported that they would probably or definitely get vaccinated as a function of time since the first day of vaccination. The model was used to predict an average scale global curve for the predicted percentage of the population that is likely to be vaccinated. The resulting scale-up curve approximates better the observed slowing rate of vaccination as countries approach the maximum number of people who are willing to get vaccinated. The average scale-up curve was calibrated to the observed number of vaccinations reported to be delivered in each location. This was done by calculating the ratio of the predicted cumulative percentage vaccinated over the observed percentage vaccinated for the most recent time period. This ratio was then used to adjust the average scale-up curve. For locations without observed data, we used the regional average ratio to calibrate the scale-up curve.

Our previous model update, made the week of May 3, included the transition to measuring total COVID-19 mortality; more details are available here.

Figure 3. Daily COVID-19 death rate per 1 million on May 24, 2021

Figure 4. Cumulative COVID-19 deaths per 100,000 on May 24, 2021
Figure 5. Estimated percent of the population infected with COVID-19 on May 24, 2021

Figure 6. Mean effective R on May 13, 2021. The estimate of effective R is based on the combined analysis of deaths, case reporting, and hospitalizations where available. Current reported cases reflect infections 11-13 days prior, so estimates of effective R can only be made for the recent past. Effective R less than 1 means that transmission should decline, all other things being held the same.
Figure 7. Percent of COVID-19 infections detected. This is estimated as the ratio of reported daily COVID-19 cases to estimated daily COVID-19 infections based on the SEIR disease transmission model.

*Due to measurement errors in cases and testing rates, the infection to detection rate (IDR) can exceed 100% at particular points in time.

Figure 17. Trend in the estimated proportion of the adult (18+) population that have been vaccinated or would probably or definitely receive the COVID-19 vaccine if available.

Figure 18. This figure shows the estimated proportion of the adult (18+) population that has been vaccinated or would probably or definitely receive the COVID-19 vaccine if available.
Figure 19. The number of people who receive any vaccine and those who are effectively vaccinated and protected against disease, accounting for efficacy, loss to follow up for two-dose vaccines, partial immunity after one dose, and immunity after two doses.
Projections and scenarios

We produce three scenarios when projecting COVID-19. The reference scenario is our forecast of what we think is most likely to happen:

- Vaccines are distributed at the expected pace.
- Governments adapt their response by re-imposing social distancing mandates for 6 weeks whenever daily deaths reach 8 per million, unless a location has already spent at least 7 of the last 14 days with daily deaths above this rate and not yet re-imposed social distancing mandates. In this case, the scenario assumes that mandates are re-imposed when daily deaths reach 15 per million.
- Variants B.1.1.7 (first identified in the UK), B.1.351 (first identified in South Africa), and P1 (first identified in Brazil) continue to spread from locations with (a) more than 5 sequenced variants, and (b) reports of community transmission, to adjacent locations following the speed of variant scale-up observed in the regions of the UK.
- In one-quarter of those vaccinated, mobility increases toward pre-COVID-19 levels.

The worse scenario modifies the reference scenario assumptions in three ways:

- First, it assumes that variants B.1.351 or P1 begin to spread within 3 weeks in adjacent locations that do not already have B.1.351 or P1 community transmission.
- Second, it assumes that all those vaccinated increase their mobility toward pre-COVID-19 levels.
- Third, it assumes that among those vaccinated, mask use starts to decline exponentially one month after completed vaccination.

The universal masks scenario makes all the same assumptions as the reference scenario but also assumes 95% of the population wear masks in public in every location.
Figure 20. Cumulative COVID-19 deaths until September 01, 2021 for three scenarios.

Figure 21. Daily COVID-19 deaths until September 01, 2021 for three scenarios.
Figure 22. Daily COVID-19 infections until September 01, 2021 for three scenarios.
Figure 23. Comparison of reference model projections with other COVID modeling groups. For this comparison, we are including projections of daily COVID-19 deaths from other modeling groups when available: Delphi from the Massachusetts Institute of Technology (Delphi; https://www.covidanalytics.io/home), Imperial College London (Imperial; https://www.covidsim.org), The Los Alamos National Laboratory (LANL; https://covid-19.bsvgateway.org/), and the SI-KJalpha model from the University of Southern California (SIKJalpha; https://github.com/scc-usc/ReCOVER-COVID-19). Daily deaths from other modeling groups are smoothed to remove inconsistencies with rounding. Regional values are aggregates from available locations in that region.
**Figure 24.** The estimated inpatient hospital usage is shown over time. The percent of hospital beds occupied by COVID-19 patients is color coded based on observed quantiles of the maximum proportion of beds occupied by COVID-19 patients. Less than 5% is considered low stress, 5-9% is considered moderate stress, 10-19% is considered high stress, and greater than 20% is considered extreme stress.
Figure 25. The estimated intensive care unit (ICU) usage is shown over time. The percent of ICU beds occupied by COVID-19 patients is color coded based on observed quantiles of the maximum proportion of ICU beds occupied by COVID-19 patients. Less than 10% is considered low stress, 10-29% is considered moderate stress, 30-59% is considered high stress, and greater than 60% is considered extreme stress.
More information

Data sources:
Mask use and vaccine confidence data are from the Global COVID-19 Symptom Survey (this research is based on survey results from University of Maryland Social Data Science Center with Facebook’s support) and the US COVID-19 Symptom Survey (this research is based on survey results from Carnegie Mellon University’s Delphi Research Group with Facebook’s support). Mask use data are also from Premise, the Kaiser Family Foundation, and the YouGov COVID-19 Behaviour Tracker survey.

Genetic sequence and metadata are primarily from the GISAID Initiative. Further details available on the COVID-19 model FAQ page.

A note of thanks:
We wish to warmly acknowledge the support of these and others who have made our COVID-19 estimation efforts possible.
