COVID-19 Results Briefing
Russian Federation

September 2, 2021

This document contains summary information on the latest projections from the IHME model on COVID-19 in Russian Federation. The model was run on August 31, 2021, with data through August 30, 2021.

Current situation

- Daily infections in the last week decreased to 301,000 per day on average compared to 408,500 the week before. (Figure 1). Daily hospital census in the last week (through August 30) increased to 130,500 per day on average compared to 129,700 the week before.
- Daily reported cases in the last week decreased to 18,200 per day on average compared to 20,100 the week before (Figure 2).
- Reported deaths due to COVID-19 in the last week increased to 780 per day on average compared to 770 the week before (Figure 3).
- Excess deaths due to COVID-19 in the last week increased to 5,100 per day on average compared to 5,100 the week before (Figure 3). This makes COVID-19 the number 1 cause of death in Russian Federation this week (Table 1). Estimated excess daily deaths due to COVID-19 in the past week were 6.5 times larger than the reported number of deaths.
- The daily reported COVID-19 death rate is greater than 4 per million in Azerbaijan, Bulgaria, Georgia, Kazakhstan, Montenegro, North Macedonia, and Russian Federation (Figure 4).
- The daily rate of excess deaths due to COVID-19 is greater than 4 per million in 17 countries (Figure 4).
- We estimate that 87% of people in Russian Federation have been infected as of August 30 (Figure 6).
- Effective R, computed using cases, hospitalizations, and deaths, is greater than 1 in 66 countries (Figure 7).
- The infection-detection rate in Russian Federation was close to 4% on August 30 (Figure 8).
- Based on the GISAID and various national databases, combined with our variant spread model, we estimate the current prevalence of variants of concern (Figure 9). We estimate that the Beta variant is circulating in 1 country, that the Delta variant is circulating in 48 countries, and that the Gamma variant is circulating in 28 countries.

Trends in drivers of transmission

- Mobility last week was 8% lower than the pre-COVID-19 baseline (Figure 11). Mobility was near baseline (within 10%) in 40 countries. Mobility was lower than 30% of baseline in Kazakhstan.
- As of August 30, in the COVID-19 Trends and Impact Survey, 43% of people self-report that they always wore a mask when leaving their home compared to 43% last week (Figure 13).
- There were 327 diagnostic tests per 100,000 people on August 30 (Figure 15).
- As of August 30, 13 countries have reached 70% or more of the population who have received at least one vaccine dose and 7 countries have reached 70% or more of the population who are fully vaccinated (Figure 17).
- In Russian Federation, 45.1% of people say they would accept or would probably accept a vaccine for COVID-19. This is up by 1.3 percentage points from last week. The proportion of the population who are open to receiving a COVID-19 vaccine ranges from 34% in Bulgaria to 85% in Portugal (Figure 19).
- In our current reference scenario, we expect that 48.2 million people will be vaccinated with at least one dose by December 1 (Figure 20).
- In our current reference scenario, we expect that by December 1, 93% of people will be immune to non-escape variants and 84% of people will be immune to escape variants (Figure 21).
Projections

- In our **reference scenario**, which represents what we think is most likely to happen, our model projects 201,000 cumulative reported deaths due to COVID-19 on December 1. This represents 22,000 additional deaths from August 30 to December 1. Daily reported deaths will decline to 10 on December 1, 2021 (Figure 22).

- Under our **reference scenario**, our model projects 1,315,000 cumulative excess deaths due to COVID-19 on December 1. This represents 142,000 additional deaths from August 30 to December 1 (Figure 22).

- If **universal mask coverage (95%)** were attained in the next week, our model projects 2,300 fewer cumulative reported deaths compared to the reference scenario on December 1.

- Under our **worse scenario**, our model projects 204,000 cumulative reported deaths on December 1, an additional 2,700 deaths compared to our reference scenario. Daily reported deaths in the **worse scenario** will decline to 40 on December 1, 2021 (Figure 22).

- Daily infections in the **reference scenario** will decline to 7,600 on December 1, 2021 (Figure 23). Daily infections in the **worse scenario** will decline to 26,000 by November 28, 2021 (Figure 23).

- Daily cases in the **reference scenario** will decline to 360 on December 1, 2021 (Figure 24). Daily cases in the **worse scenario** will decline to 1,180 on December 1, 2021 (Figure 24).

- Daily hospital census in the **reference scenario** will decline to 2,860 on December 1, 2021 (Figure 25). Daily hospital census in the **worse scenario** will decline to 8,770 on December 1, 2021 (Figure 25).

- Figure 26 compares our reference scenario forecasts to other publicly archived models. Forecasts are widely divergent.

- At some point from August through December 1, 28 countries will have high or extreme stress on hospital beds (Figure 27). At some point from August through December 1, 42 countries will have high or extreme stress on intensive care unit (ICU) capacity (Figure 28).
Model updates
For 22 US states, we have observed poor temporal concordance over recent weeks when comparing (a) deaths, hospitalizations, and cases to (b) seroprevalence surveys after performing assay-specific corrections for sero-reversion. To improve this, we changed the assumptions in the model as to which assay was used in those particular states – from one with substantial declines in sensitivity over time to one with more robust long-term sensitivity – which resulted in a smaller adjustment for these data, and thus lower estimates of seroprevalence. The below are examples from Florida. The top figure shows the previous approach; the lower figure shows the new approach. Squares are reported, circles are post-correction.

Figure 6. Estimated percent of the population infected with COVID-19 on August 30, 2021.

Figure 7. Mean effective R on August 19, 2021. Effective R less than 1 means that transmission should decline, all other things being held the same. The estimate of effective R is based on the combined analysis of deaths, case reporting, and hospitalizations where available. Current reported cases reflect infections 11-13 days prior, so estimates of effective R can only be made for the recent past.
**Figure 8.** Percent of COVID-19 infections detected. This is estimated as the ratio of reported daily COVID-19 cases to estimated daily COVID-19 infections based on the SEIR disease transmission model. Due to measurement errors in cases and testing rates, the infection-detection rate can exceed 100% at particular points in time.

Table 3. Estimates of vaccine efficacy for specific vaccines used in the model at preventing disease and infection. The SEIR model uses variant-specific estimates of vaccine efficacy at preventing symptomatic disease and at preventing infection. We use data from clinical trials directly, where available, and make estimates otherwise. More information can be found on our website.

Projections and scenarios

We produce three scenarios when projecting COVID-19. The **reference scenario** is our forecast of what we think is most likely to happen:

- Vaccines are distributed at the expected pace. Brand- and variant-specific vaccine efficacy is updated using the latest available information from peer-reviewed publications and other reports.
- Future mask use is the mean of mask use over the last 7 days.
- Mobility increases as vaccine coverage increases.
- Governments adapt their response by re-imposing social distancing mandates for 6 weeks whenever daily deaths reach 8 per million, unless a location has already spent at least 7 of the last 14 days with daily deaths above this rate, and not yet re-imposed social distancing mandates. In this case, the reference scenario assumes that mandates are re-imposed when daily deaths reach 15 per million.
- Variants Alpha, Beta, Gamma, and Delta continue to spread regionally and globally from locations with sufficient transmission.

The **worse scenario** modifies the reference scenario assumption in four ways:

- 100% of vaccinated individuals stop using masks.
- Mobility increases in all locations to 25% above the pre-pandemic winter baseline, irrespective of vaccine coverage.
- Governments are more reluctant to re-impose social distancing mandates, waiting until the daily death rate reaches 15 per million, unless a location has already spent at least 7 of the last 14 days with daily deaths above this rate, and not yet re-imposed social distancing mandates. In this case, the reference scenario assumes that mandates are re-imposed when daily deaths reach 38 per million. In either case, we assume social distancing mandates remain in effect for 6 weeks.
- Variants Alpha, Beta, Gamma, and Delta spread between locations twice as fast when compared with our reference scenario.

The **universal masks scenario** makes all the same assumptions as the reference scenario but assumes all locations reach 95% mask use within 7 days.
Figure 22. Daily COVID-19 deaths until December 01, 2021 for three scenarios

A. Reported daily COVID-19 deaths per 100,000

B. Excess daily COVID-19 deaths per 100,000
**Figure 23.** Daily COVID-19 infections until December 01, 2021 for three scenarios

**Figure 24.** Daily COVID-19 reported cases until December 01, 2021 for three scenarios
Figure 25. Daily COVID-19 hospital census until December 01, 2021 for three scenarios

Figure 26. Comparison of reference model projections with other COVID modeling groups. For this comparison, we are including projections of daily COVID-19 deaths from other modeling groups when available: Delphi from the Massachusetts Institute of Technology (Delphi), Imperial College London (Imperial), The Los Alamos National Laboratory (LANL), and the SI-KJalpha model from the University of Southern California (SIKJalpha). Daily deaths from other modeling groups are smoothed to remove inconsistencies with rounding. Regional values are aggregates from available locations in that region.
**Figure 27.** The estimated inpatient hospital usage is shown over time. The percent of hospital beds occupied by COVID-19 patients is color-coded based on observed quantiles of the maximum proportion of beds occupied by COVID-19 patients. Less than 5% is considered low stress, 5-9% is considered moderate stress, 10-19% is considered high stress, and 20% or greater is considered extreme stress.
Figure 28. The estimated intensive care unit (ICU) usage is shown over time. The percent of ICU beds occupied by COVID-19 patients is color-coded based on observed quantiles of the maximum proportion of ICU beds occupied by COVID-19 patients. Less than 10% is considered low stress, 10-29% is considered moderate stress, 30-59% is considered high stress, and 60% or greater is considered extreme stress.
More information

Data sources:
Mask use and vaccine confidence data are from the The Delphi Group at Carnegie Mellon University and University of Maryland COVID-19 Trends and Impact Surveys, in partnership with Facebook. Mask use data are also from Premise, the Kaiser Family Foundation, and the YouGov COVID-19 Behaviour Tracker survey.
Genetic sequence and metadata are primarily from the GISAID Initiative. Further details available on the COVID-19 model FAQ page.

A note of thanks:
We wish to warmly acknowledge the support of these and others who have made our COVID-19 estimation efforts possible.
