COVID-19 Results Briefing

The African Region

October 1, 2021

This document contains summary information on the latest projections from the IHME model on COVID-19 in the African Region. The model was run on September 28, 2021, with data through September 27, 2021.

Estimated daily infections, reported cases, hospitalizations, and reported deaths continue to decrease across the African region as the current Delta surge continues to recede. However, we are seeing increasing transmission in 16 countries, where effective R is greater than 1. In our reference scenario, we expect daily reported cases and deaths to continue decreasing through mid-October, after which we expect infections, cases, and deaths to climb through the end of the year. We project 173,000 deaths by the end of the year, representing 30,000 additional reported deaths from September 27 to January 1; universal mask use could save 16,000 lives. As we go into fall and more countries ease restrictions, these trends may be exacerbated by high mobility (currently 16% higher than the pre-COVID baseline) and low mask use (currently 49% reporting wearing a mask when leaving the home). Strategies for addressing the pandemic in the coming months include: 1) promoting mask use and implementing other appropriate social distancing mandates to curb transmission. 2) Addressing global vaccine inequities by tackling supply constraints, including accelerated vaccine donations allocated to countries where needs are highest. 3) Messaging the safety and efficacy of available COVID-19 vaccines to hesitant populations. 4) Improved monitoring of seroprevalence, particularly in countries where the infection-detection rate continues to be low and considerable uncertainty exists about the extent of past infections. 5) Monitoring of the impact of vaccination and potential waning of immunity through reporting of cases, hospitalizations, and deaths, disaggregated by vaccination status. Given the available evidence on waning immunity and lower efficacy of vaccines preventing infection as compared to hospitalization and death, strategies to reduce COVID-19 transmission to zero are unlikely to succeed. Ongoing COVID-19 transmission and burden on the health system are likely to extend past the forecast period and well into 2022 and beyond.

Current situation

- Daily infections in the last week increased to 311,700 per day on average compared to 306,000 the week before (Figure 1). Daily hospital census in the last week (through September 27) decreased to 39,400 per day on average compared to 45,100 the week before.

- Daily reported cases in the last week decreased to 13,600 per day on average compared to 17,300 the week before (Figure 2).

- Reported deaths due to COVID-19 in the last week decreased to 260 per day on average compared to 300 the week before (Figure 3).
• Excess deaths due to COVID-19 in the last week decreased to 790 per day on average compared to 870 the week before (Figure 3). This makes COVID-19 the number 9 cause of death in the African Region this week (Table 1). Estimated excess daily deaths due to COVID-19 in the past week were 3 times larger than the reported number of deaths.

• No locations had daily reported COVID-19 death rates greater than 4 per million (Figure 4).

• The daily rate of excess deaths due to COVID-19 is greater than 4 per million in Eswatini, Mauritius, Sao Tome and Principe, and South Africa (Figure 4).

• We estimate that 20% of people in the African Region have been infected as of September 27 (Figure 6).

• Effective R, computed using cases, hospitalizations, and deaths, is greater than 1 in 16 countries. (Figure 7).

• The infection-detection rate in the African Region was close to 3% on September 27 (Figure 8).

• Based on the GISAID and various national databases, combined with our variant spread model, we estimate the current prevalence of variants of concern (Figure 9). We estimate that the Beta variant is circulating in 2 countries, that the Delta variant is circulating in 41 countries, and that the Gamma variant is circulating in 8 countries.

Trends in drivers of transmission

• Mobility last week was 16% higher than the pre-COVID-19 baseline (Figure 11). Mobility was near baseline (within 10%) in 44 countries. Mobility was lower than 30% of baseline in no locations.

• As of September 27, in the COVID-19 Trends and Impact Survey, 49% of people self-report that they always wore a mask when leaving their home, the same as last week (Figure 13).

• There were 17 diagnostic tests per 100,000 people on September 27 (Figure 15).

• As of September 27, 1 country has reached 70% or more of the population who have received at least one vaccine dose and 1 country has reached 70% or more of the population who are fully vaccinated (Figure 17).

• In the African Region, 59.5% of the population that is 12 years and older say they would accept or would probably accept a vaccine for COVID-19. Note that vaccine acceptance is calculated using survey data from the 18+ population. This is down by 0.5 percentage points from last week. The proportion of the population who are open to receiving a COVID-19 vaccine ranges from 32% in Botswana to 74% in Guinea (Figure 19).

• In our current reference scenario, we expect that 137.3 million people will be vaccinated with at least one dose by January 1 (Figure 20). We expect that 6% of the population will be fully vaccinated by January 1.
Based on the estimate of the population that have been infected with COVID-19 and vaccinated to date, combined with assumptions on protection against infection with the Delta variant provided by either natural infection, vaccination, or both, we estimate that 17% of the region is immune to the Delta variant. In our current reference scenario, we expect that by January 1, 27% of people will be immune to the Delta variant (Figure 21). These two calculations do not take into account waning of natural or vaccine-derived immunity.

Projections

- In our reference scenario, which represents what we think is most likely to happen, our model projects 173,000 cumulative reported deaths due to COVID-19 on January 1. This represents 30,000 additional deaths from September 27 to January 1. Daily reported deaths will decline to 190 by October 19, 2021 (Figure 22).

- Under our reference scenario, our model projects 513,000 cumulative excess deaths due to COVID-19 on January 1. This represents 99,000 additional deaths from September 27 to January 1 (Figure 22).

- If universal mask coverage (95%) were attained in the next week, our model projects 16,000 fewer cumulative reported deaths compared to the reference scenario on January 1.

- Under our worse scenario, our model projects 182,000 cumulative reported deaths on January 1, an additional 8,700 deaths compared to our reference scenario. Daily reported deaths in the worse scenario will decline to 190 by October 17, 2021 (Figure 22).

- Daily infections in the reference scenario will rise to 2,144,860 on January 1, 2022 (Figure 23). Daily infections in the worse scenario will rise to 2,888,060 by December 31, 2021 (Figure 23).

- Daily cases in the reference scenario will decline to 7,470 by October 4, 2021 (Figure 24). Daily cases in the worse scenario will decline to 7,490 by October 3, 2021 (Figure 24).

- Daily hospital census in the reference scenario will decline to 32,630 by October 13, 2021 (Figure 25). Daily hospital census in the worse scenario will decline to 32,940 by October 11, 2021 (Figure 25).

- Figure 26 compares our reference scenario forecasts to other publicly archived models. Forecasts are widely divergent.

- At some point from September through January 1, 27 countries will have high or extreme stress on hospital beds (Figure 27). At some point from September through January 1, 38 countries will have high or extreme stress on intensive care unit (ICU) capacity (Figure 28).
Model updates

We have revised the number of reported deaths for Mexican states as well as the Russian Federation away from numbers derived from routine surveillance to those sourced from national cause of death registries. In these two countries, we have seen substantial differences between reported deaths and those assigned to COVID through the death certification review process. Given that deaths recorded in cause of death registries neither span the total time series nor provide daily values, but monthly, we have made the following assumptions to compute a new time series: (a) that the pattern in daily deaths in the cause of death data follows the patterning present in the daily reported series for days within a given month, and (b) that the ratio of monthly reported deaths to monthly deaths registered in cause of death analysis is constant from the last common time period to today. The total excess death estimate is not affected by this change to the reported time series.

Figure 7. Mean effective R on September 16, 2021. Effective R less than 1 means that transmission should decline, all other things being held the same. The estimate of effective R is based on the combined analysis of deaths, case reporting, and hospitalizations where available. Current reported cases reflect infections 11-13 days prior, so estimates of effective R can only be made for the recent past.
Figure 8. Percent of COVID-19 infections detected. This is estimated as the ratio of reported daily COVID-19 cases to estimated daily COVID-19 infections based on the SEIR disease transmission model. Due to measurement errors in cases and testing rates, the infection-detection rate can exceed 100% at particular points in time.

Projections and scenarios

We produce three scenarios when projecting COVID-19. The **reference scenario** is our forecast of what we think is most likely to happen:

- Vaccines are distributed at the expected pace. Brand- and variant-specific vaccine efficacy is updated using the latest available information from peer-reviewed publications and other reports.
- Future mask use is the mean of mask use over the last 7 days.
- Mobility increases as vaccine coverage increases.
- Governments adapt their response by re-imposing social distancing mandates for 6 weeks whenever daily deaths reach 8 per million, unless a location has already spent at least 7 of the last 14 days with daily deaths above this rate, and not yet re-imposed social distancing mandates. In this case, the reference scenario assumes that mandates are re-imposed when daily deaths reach 15 per million.
- Variants Alpha, Beta, Gamma, and Delta continue to spread regionally and globally from locations with sufficient transmission.

The **worse scenario** modifies the reference scenario assumption in four ways:

- 100% of vaccinated individuals stop using masks.
- Mobility increases in all locations to 25% above the pre-pandemic winter baseline, irrespective of vaccine coverage.
- Governments are more reluctant to re-impose social distancing mandates, waiting until the daily death rate reaches 15 per million, unless a location has already spent at least 7 of the last 14 days with daily deaths above this rate, and not yet re-imposed social distancing mandates. In this case, the reference scenario assumes that mandates are re-imposed when daily deaths reach 38 per million. In either case, we assume social distancing mandates remain in effect for 6 weeks.
- Variants Alpha, Beta, Gamma, and Delta spread between locations twice as fast when compared with our reference scenario.

The **universal masks scenario** makes all the same assumptions as the reference scenario but assumes all locations reach 95% mask use within 7 days.
Figure 22. Daily COVID-19 deaths until January 01, 2022 for three scenarios

**Figure 24.** Daily COVID-19 reported cases until January 01, 2022 for three scenarios
Figure 25. Daily COVID-19 hospital census until January 01, 2022 for three scenarios
Figure 26. Comparison of reference model projections with other COVID modeling groups. For this comparison, we are including projections of daily COVID-19 deaths from other modeling groups when available, last model update in brackets: Delphi from the Massachusetts Institute of Technology (Delphi) [September 22, 2021], Imperial College London (Imperial) [September 9, 2021], The Los Alamos National Laboratory (LANL) [September 19, 2021], the SI-KJalpha model from the University of Southern California (SIKJalpha) [September 22, 2021]. Daily deaths from other modeling groups are smoothed to remove inconsistencies with rounding. Regional values are aggregates from available locations in that region.
Figure 27. The estimated inpatient hospital usage is shown over time. The percent of hospital beds occupied by COVID-19 patients is color-coded based on observed quantiles of the maximum proportion of beds occupied by COVID-19 patients. Less than 5% is considered low stress, 5-9% is considered moderate stress, 10-19% is considered high stress, and 20% or greater is considered extreme stress.
**Figure 28.** The estimated intensive care unit (ICU) usage is shown over time. The percent of ICU beds occupied by COVID-19 patients is color-coded based on observed quantiles of the maximum proportion of ICU beds occupied by COVID-19 patients. Less than 10% is considered *low stress*, 10-29% is considered *moderate stress*, 30-59% is considered *high stress*, and 60% or greater is considered *extreme stress*. 

The chart shows the stress level of various countries as of different dates from March 20 to January 2022.
More information

Data sources:
Mask use and vaccine confidence data are from the The Delphi Group at Carnegie Mellon University and University of Maryland COVID-19 Trends and Impact Surveys, in partnership with Facebook. Mask use data are also from Premise, the Kaiser Family Foundation, and the YouGov COVID-19 Behaviour Tracker survey.
Genetic sequence and metadata are primarily from the GISAID Initiative. Further details available on the COVID-19 model FAQ page.

A note of thanks:
We wish to warmly acknowledge the support of these and others who have made our COVID-19 estimation efforts possible.
