COVID-19 Results Briefing

Mongolia

July 22, 2021

This document contains summary information on the latest projections from the IHME model on COVID-19 in Mongolia. The model was run on July 20, 2021, with data through July 18, 2021.

Current situation

• Daily reported cases in the last week (through July 18) decreased to 1,300 per day on average compared to 1,700 the week before (Figure 1).
• Reported deaths due to COVID-19 in the last week decreased to 6 per day on average compared to 9 the week before (Figure 2).
• Excess deaths due to COVID-19 in the last week decreased to 21 per day on average compared to 32 the week before (Figure 2). This makes COVID-19 the number 1 cause of death in Mongolia this week (Table 1). Estimated excess daily deaths due to COVID-19 were 3.7 times larger than the reported number of deaths.
• The daily reported COVID-19 death rate is greater than 4 per million in Fiji, and Malaysia (Figure 3).
• The daily rate of excess deaths due to COVID-19 is greater than 4 per million in Cambodia, Fiji, Malaysia, and Mongolia (Figure 3).
• We estimated that 21% of people in Mongolia have been infected as of July 19 (Figure 5).
• Effective R, computed using cases, hospitalizations, and deaths, is greater than 1 in 18 countries (Figure 6). The Effective R in Mongolia on July 8 was 0.84.
• The infection-detection rate in Mongolia was close to 28% on July 19 (Figure 7).
• Based on the GISAID and various national databases, combined with our variant spread model, we estimate the current prevalence of variants of concern (Figure 8). We estimate that B.1.351 is circulating in 1 countries, that B.1.617 is circulating in 12 countries, and that P.1 is circulating in 0 countries.

Trends in drivers of transmission

• Mobility last week was 29% higher than the pre-COVID-19 baseline (Figure 10). Mobility was near baseline (within 10%) in Brunei Darussalam, China, Mongolia, New Zealand, Papua New Guinea, and Republic of Korea. Mobility was lower than 30% of baseline in Cambodia, Fiji, Lao People’s Democratic Republic, Malaysia, and Viet Nam.
• As of July 19, in the COVID-19 Trends and Impact Survey, 65% of people self-report that they always wore a mask when leaving their home compared to 65% last week (Figure 12).
• There were 270 diagnostic tests per 100,000 people on July 19 (Figure 14).
• In Mongolia 52.9% of people say they would accept or would probably accept a vaccine for COVID-19. This is up by 0.5 percentage points from last week. The fraction of the population who are open to receiving a COVID-19 vaccine ranges from 53% in Mongolia to 92% in Malaysia (Figure 18).
• In our current reference scenario, we expect that 2.0 million people will be vaccinated by November 1 (Figure 19).
• In our current reference scenario, we expect that by November 1, 65% of people will be immune to non-escape variants and 55% of people will be immune to escape variants (Figure 20).
Projections

- In our reference scenario, which represents what we think is most likely to happen, our model projects 1,400 cumulative reported deaths due to COVID-19 on November 1. This represents 690 additional deaths from July 19 to November 1. Daily reported deaths will decline to 0 by August 20, 2021 (Figure 21).

- Under our reference scenario, our model projects 5,300 cumulative excess deaths due to COVID-19 on November 1. This represents 3,000 additional deaths from July 19 to November 1. Daily excess deaths due to COVID-19 will decline to 10 by August 20, 2021 (Figure 21).

- If universal mask coverage (95%) were attained in the next week, our model projects 510 fewer cumulative reported deaths compared to the reference scenario on November 1.

- If universal mask coverage (95%) were attained in the next week, our model projects 1,900 fewer cumulative excess deaths due to COVID-19 compared to the reference scenario on November 1.

- Under our worse scenario, our model projects 1,600 cumulative reported deaths on November 1, an additional 160 deaths compared to our reference scenario. Daily reported deaths in the worse scenario will rise to 10 by October 31, 2021 (Figure 21).

- Under our worse scenario, our model projects 5,900 cumulative excess deaths due to COVID-19 on November 1, an additional 630 deaths compared to our reference scenario. Daily excess deaths due to COVID-19 in the worse scenario will rise to 50 by October 31, 2021 (Figure 21).

- Daily infections in the reference scenario will rise to 17,600 by October 21, 2021 (Figure 26). Daily infections in the worse scenario will rise to 14,740 by October 7, 2021 (Figure 26).

- By November 1, we project that 200 lives will be saved by the projected vaccine rollout. This does not include lives saved through vaccination that has already been delivered.

- Figure 23 compares our reference scenario forecasts to other publicly archived models. Forecasts are widely divergent.

- At some point from July through November 1, 8 countries will have high or extreme stress on hospital beds (Figure 24). At some point from July through November 1, 9 countries will have high or extreme stress on intensive care unit (ICU) capacity (Figure 25).
Model updates

Our mobility covariate that is used in the projections of COVID infections and deaths was updated to account for observed sustained levels of high mobility. Specifically, the mobility forecasts used in both the reference and universal mask coverage projection scenarios were adjusted upward according to vaccine uptake. This is equivalent to what was previously used in the worse projection scenario. To produce vaccine-adjusted mobility forecasts, we assume that social distancing mandates decline exponentially with respect to increasing vaccine uptake such that all mandates are lifted 30 days after vaccine coverage reaches 75%. In locations where vaccine uptake is already high, projected mandates are ramped down linearly from the current value to the vaccine-adjusted value over a 30-day period. As a final change, for locations whose last day of data indicates mobility levels above baseline (defined as average mobility during the period 1/3/2020 to 2/6/2020), we no longer cap forecasted mobility at zero. The variant spread model was updated to allow for spread to have occurred in the past in locations with some variant surveillance when there was little to no sequence data to confirm or reject the potential invasion.

**Figure 5.** Estimated percent of the population infected with COVID-19 on July 19, 2021

**Figure 6.** Mean effective R on July 8, 2021. The estimate of effective R is based on the combined analysis of deaths, case reporting, and hospitalizations where available. Current reported cases reflect infections 11-13 days prior, so estimates of effective R can only be made for the recent past. Effective R less than 1 means that transmission should decline, all other things being held the same.
Figure 7. Percent of COVID-19 infections detected. This is estimated as the ratio of reported daily COVID-19 cases to estimated daily COVID-19 infections based on the SEIR disease transmission model. Due to measurement errors in cases and testing rates, the infection-detection rate can exceed 100% at particular points in time.

Figure 20. Percentage of people who are immune to non-escape variants and the percentage of people who are immune to escape variants.
Projections and scenarios

We produce three scenarios when projecting COVID-19. The reference scenario is our forecast of what we think is most likely to happen:

- Vaccines are distributed at the expected pace.
- Governments adapt their response by re-imposing social distancing mandates for 6 weeks whenever daily deaths reach 8 per million, unless a location has already spent at least 7 of the last 14 days with daily deaths above this rate and not yet re-imposed social distancing mandates. In this case, the scenario assumes that mandates are re-imposed when daily deaths reach 15 per million.
- Variants B.1.1.7 (first identified in the UK), B.1.351 (first identified in South Africa), and P1 (first identified in Brazil) continue to spread from locations with (a) more than 5 sequenced variants, and (b) reports of community transmission, to adjacent locations following the speed of variant scale-up observed in the regions of the United Kingdom.
- In one-quarter of those vaccinated, mobility increases toward pre-COVID-19 levels.

The worse scenario modifies the reference scenario assumptions in three ways:

- First, it assumes that variants B.1.351 or P.1 begin to spread within three weeks in adjacent locations that do not already have B.1.351 or P.1 community transmission.
- Second, it assumes that all those vaccinated increase their mobility toward pre-COVID-19 levels.
- Third, it assumes that among those vaccinated, mask use starts to decline exponentially one month after completed vaccination.

The universal masks scenario makes all the same assumptions as the reference scenario but also assumes 95% of the population wear masks in public in every location.
Figure 21. Daily COVID-19 deaths until November 01, 2021 for three scenarios

A. Reported daily COVID-19 death per 100,000

B. Excess daily COVID-19 deaths per 100,000
Figure 22. Daily COVID-19 infections until November 01, 2021 for three scenarios
Figure 23. Comparison of reference model projections with other COVID modeling groups. For this comparison, we are including projections of daily COVID-19 deaths from other modeling groups when available: Delphi from the Massachusetts Institute of Technology (Delphi), Imperial College London (Imperial), The Los Alamos National Laboratory (LANL), and the SI-KJalpha model from the University of Southern California (SIKJalpha). Daily deaths from other modeling groups are smoothed to remove inconsistencies with rounding. Regional values are aggregates from available locations in that region.
Figure 24. The estimated inpatient hospital usage is shown over time. The percent of hospital beds occupied by COVID-19 patients is color-coded based on observed quantiles of the maximum proportion of beds occupied by COVID-19 patients. Less than 5% is considered low stress, 5-9% is considered moderate stress, 10-19% is considered high stress, and 20% or greater is considered extreme stress.
**Figure 25.** The estimated intensive care unit (ICU) usage is shown over time. The percent of ICU beds occupied by COVID-19 patients is color-coded based on observed quantiles of the maximum proportion of ICU beds occupied by COVID-19 patients. Less than 10% is considered *low stress*, 10-29% is considered *moderate stress*, 30-59% is considered *high stress*, and 60% or greater is considered *extreme stress*.
More information

Data sources:
Mask use and vaccine confidence data are from the The Delphi Group at Carnegie Mellon University and University of Maryland COVID-19 Trends and Impact Surveys, in partnership with Facebook. Mask use data are also from Premise, the Kaiser Family Foundation, and the YouGov COVID-19 Behaviour Tracker survey. Genetic sequence and metadata are primarily from the GISAID Initiative. Further details available on the COVID-19 model FAQ page.

A note of thanks:
We wish to warmly acknowledge the support of these and others who have made our COVID-19 estimation efforts possible.
