COVID-19 Results Briefing

The Western Pacific Region

November 18, 2021

This document contains summary information on the latest projections from the IHME model on COVID-19 in the Western Pacific Region. The model was run on November 16, 2021, with data through November 15, 2021.

In the Western Pacific Region, daily infections and reported cases are increasing and effective R is greater than 1 in 10 locations, including South Korea, Vietnam, and Malaysia. The increase is most likely driven by the easing of restrictions, waning vaccine-derived immunity, and decreasing physical distancing behaviors, as the mobility level climbed to 5% below the pre-COVID-19 baseline regionally. Although there has been a decline in hospitalizations and reported deaths, we expect that this trend will reverse and daily reported deaths will rise to 380 by December 29, 2021.

In our reference scenario, we project 171,000 cumulative reported deaths due to COVID-19 on March 1, representing 37,000 additional deaths from November 15 to March 1. As our model does not explicitly take into account the waning of natural or vaccine-derived immunity, these estimates might be optimistic. Evidence is accumulating that vaccine-derived immunity wanes substantially by 30 weeks, and patterns in Europe suggest that immunity from natural infection may wane more slowly than vaccine-derived immunity. These are important factors for the Western Pacific Region as we estimate that only 4% of people in the region have been infected as of November 15. Our projections that explicitly model the waning of natural and vaccine-derived immunity will likely be released in early December. It is already clear from the testing and development of this new model that we may see even larger surges in the early months of 2022 in some countries. Winter seasonality and increasing mobility during holiday seasons are expected to further increase transmission levels.

Strategies for policymakers to address future surges can be grouped into three categories: First, promoting health-protective behaviors, such as physical distancing and mask use, to reduce transmission. Our model indicates that if universal mask use (95%) could be achieved, 8,500 lives could be saved. Second, increasing vaccinations by increasing vaccine donations to supply-constrained locations, reducing barriers for local manufacturing and distribution, and addressing vaccine hesitancy through countering misinformation and addressing the contextual influences. Third, delivering a COVID-19 booster shot, focusing on at-risk populations first, in locations with more favorable vaccine supplies. Consistent implementation of some combination of all three of these strategies may be able to reduce transmission, prevent health care systems from becoming overwhelmed, and save lives in the coming months.
Current situation

- Daily infections in the last week increased to 193,400 per day on average compared to 187,300 the week before (Figure 1.1). Daily hospital census in the last week (through November 15) decreased to 24,500 per day on average compared to 25,500 the week before.

- Daily reported cases in the last week increased to 24,800 per day on average compared to 23,700 the week before (Figure 2.1).

- Reported deaths due to COVID-19 in the last week remained constant at 240 per day on average (Figure 3.1).

- Total deaths due to COVID-19 in the last week decreased to 570 per day on average compared to 580 the week before (Figure 3.1). This makes COVID-19 the number 16 cause of death in Western Pacific Region this week (Table 1). Estimated total daily deaths due to COVID-19 in the past week were 2.4 times larger than the reported number of deaths.

- No locations had daily reported COVID-19 death rates greater than 4 per million (Figure 4.1).

- The daily rate of total deaths due to COVID-19 is greater than 4 per million in Laos and Papua New Guinea (Figure 4.2).

- We estimate that 4% of people in Western Pacific Region have been infected as of November 15 (Figure 6.1).

- Effective R, computed using cases, hospitalizations, and deaths, is greater than 1 in 10 locations (Figure 7.1).

- The infection-detection rate in Western Pacific Region was close to 14% on November 15 (Figure 8.1).

- Based on the GISAID and various national databases, combined with our variant spread model, we estimate the current prevalence of variants of concern (Figure 9.1). We estimate that the Beta variant is circulating in one country, that the Delta variant is circulating in 13 countries, and that the Gamma variant is circulating in no countries in the region.

Trends in drivers of transmission

- Mobility last week was 5% lower than the pre-COVID-19 baseline (Figure 11.1). Mobility was near baseline (within 10%) in Brunei, China, Fiji, Mongolia, New Zealand, Papua New Guinea, South Korea, and Vanuatu. Mobility was lower than 30% of baseline in Laos.

- As of November 15, in the COVID-19 Trends and Impact Survey, 65% of people self-report that they always wore a mask when leaving their home, unchanged since last week (Figure 13.1).

- There were 139 diagnostic tests per 100,000 people on November 15 (Figure 15.1).
As of November 15, 12 countries have reached 70% or more of the population who have received at least one vaccine dose and eight countries have reached 70% or more of the population who are fully vaccinated (Figure 17.1).

In our current reference scenario, we expect that 1.6 billion people will be vaccinated with at least one dose by March 1 (Figure 20.1). We expect that 79% of the population will be fully vaccinated by March 1.

Based on the estimate of the population that have been infected with COVID-19 and vaccinated to date, combined with assumptions on protection against infection with the Delta variant provided by either natural infection, vaccination, or both, we estimate that 22% of the region is immune to the Delta variant. In our current reference scenario, we expect that by March 1, 24% of people will be immune to the Delta variant (Figure 21.1). These two calculations do not take into account waning of natural or vaccine-derived immunity.

Projections

In our reference scenario, which represents what we think is most likely to happen, our model projects 171,000 cumulative reported deaths due to COVID-19 on March 1. This represents 37,000 additional deaths from November 15 to March 1. Daily reported deaths will rise to 380 by December 29, 2021 (Figure 22.1).

Under our reference scenario, our model projects 379,000 cumulative total deaths due to COVID-19 on March 1. This represents 85,000 additional deaths from November 15 to March 1 (Figure 22.1).

If universal mask coverage (95%) were attained in the next week, our model projects 8,500 fewer cumulative reported deaths compared to the reference scenario on March 1.

Under our worse scenario, our model projects 280,000 cumulative reported deaths on March 1, an additional 109,000 deaths compared to our reference scenario. Daily reported deaths in the worse scenario will rise to 2,400 by January 26, 2022 (Figure 22.1).

Daily infections in the reference scenario will rise to 203,220 by December 3, 2021 (Figure 22.3). Daily infections in the worse scenario will rise to 1,173,680 by January 2, 2022 (Figure 22.3).

Daily cases in the reference scenario will rise to 36,460 by February 16, 2022 (Figure 22.4). Daily cases in the worse scenario will rise to 272,810 by January 15, 2022 (Figure 22.4).

Daily hospital census in the reference scenario will rise to 30,710 by February 21, 2022 (Figure 22.5). Daily hospital census in the worse scenario will rise to 206,000 by January 25, 2022 (Figure 22.5).

Figure 23.1 compares our reference scenario forecasts to other publicly archived models. Forecasts are widely divergent.
• At some point from November through March 1, one country will have high or extreme stress on hospital beds (Figure 24.1). At some point from November through March 1, seven countries will have high or extreme stress on intensive care unit (ICU) capacity (Figure 25.1).

Projections and scenarios

We produce three scenarios when projecting COVID-19. The reference scenario is our forecast of what we think is most likely to happen:

- Vaccines are distributed at the expected pace. Brand- and variant-specific vaccine efficacy is updated using the latest available information from peer-reviewed publications and other reports.
- Future mask use is the mean of mask use over the last 7 days.
- Mobility increases as vaccine coverage increases.
- Governments adapt their response by re-imposing social distancing mandates for 6 weeks whenever daily deaths reach 8 per million, unless a location has already spent at least 7 of the last 14 days with daily deaths above this rate, and not yet re-imposed social distancing mandates. In this case, the reference scenario assumes that mandates are re-imposed when daily deaths reach 15 per million.
- Variants Alpha, Beta, Gamma, and Delta continue to spread regionally and globally from locations with sufficient transmission.

The worse scenario modifies the reference scenario assumption in four ways:

- 100% of vaccinated individuals stop using masks.
- Mobility increases in all locations to 25% above the pre-pandemic winter baseline, irrespective of vaccine coverage.
- Governments are more reluctant to re-impose social distancing mandates, waiting until the daily death rate reaches 15 per million, unless a location has already spent at least 7 of the last 14 days with daily deaths above this rate, and not yet re-imposed social distancing mandates. In this case, the reference scenario assumes that mandates are re-imposed when daily deaths reach 38 per million. In either case, we assume social distancing mandates remain in effect for 6 weeks.
- Variants Alpha, Beta, Gamma, and Delta spread between locations twice as fast when compared with our reference scenario.

The universal masks scenario makes all the same assumptions as the reference scenario but assumes all locations reach 95% mask use within 7 days.
Daily COVID-19 deaths until March 01, 2022 for three scenarios

Figure 22.5. Daily COVID-19 hospital census until March 01, 2022 for three scenarios
Figure 23.1. Comparison of reference model projections with other COVID modeling groups. For this comparison, we are including projections of daily COVID-19 deaths from other modeling groups when available, last model update in brackets: Delphi from the Massachusetts Institute of Technology (Delphi) [November 17, 2021], Imperial College London (Imperial) [November 3, 2021], the SI-KJalpha model from the University of Southern California (SIKJalpha) [November 17, 2021]. Daily deaths from other modeling groups are smoothed to remove inconsistencies with rounding. Regional values are aggregates from available locations in that region.
Figure 24.1. The estimated inpatient hospital usage is shown over time. The percent of hospital beds occupied by COVID-19 patients is color-coded based on observed quantiles of the maximum proportion of beds occupied by COVID-19 patients. Less than 5% is considered low stress, 5-9% is considered moderate stress, 10-19% is considered high stress, and 20% or greater is considered extreme stress.
Figure 25.1. The estimated intensive care unit (ICU) usage is shown over time. The percent of ICU beds occupied by COVID-19 patients is color-coded based on observed quantiles of the maximum proportion of ICU beds occupied by COVID-19 patients. Less than 10% is considered low stress, 10-29% is considered moderate stress, 30-59% is considered high stress, and 60% or greater is considered extreme stress.
More information

Data sources:
Mask use and vaccine confidence data are from the The Delphi Group at Carnegie Mellon University and University of Maryland COVID-19 Trends and Impact Surveys, in partnership with Facebook. Mask use data are also from Premise, the Kaiser Family Foundation, and the YouGov COVID-19 Behaviour Tracker survey.

Genetic sequence and metadata are primarily from the GISAID Initiative. Further details available on the COVID-19 model FAQ page.

A note of thanks:
We wish to warmly acknowledge the support of these and others who have made our COVID-19 estimation efforts possible.
