COVID-19 Results Briefing

The United States of America

February 4, 2022

This document contains summary information on the latest projections from the IHME model on COVID-19 in United States of America. The model was run on February 4, 2022, with data through January 31, 2022.

As expected, the Omicron wave at the national level has peaked and has steadily declined, both in terms of reported cases and hospital admissions. Daily deaths have exceeded the level expected but appear to be peaking. The higher reported deaths than expected is in part due to many states reporting suspect deaths in their daily death totals; suspect deaths are deaths with a positive test in the last 60 days regardless of cause of death on the death certificate. Regardless of the state-by-state differences in reporting practices, the Omicron wave appears to be starting to subside.

In other countries, particularly in Europe, two patterns have emerged that may have implications for the speed of the Omicron wave decline in the US. In countries such as England or Greece, the decline in cases has leveled off. The most likely explanation for this is rapid epidemics at the local level, but differential timing of epidemics in different regions of these countries. The second pattern is the spread of the Omicron sub-variant BA2 in Denmark with an associated longer epidemic wave. Given available evidence, the potential explanations of the BA2 secondary wave are enhanced transmissibility combined with some combination of greater immune escape from infection with past variants and/or immune escape with BA1 infection. The Danish patterns have not emerged in other settings, even as BA2 continues to spread, nor has it been associated with any reported increase in severity. Further spread of BA2 could lead to a longer Omicron wave but appears unlikely to change the basic trajectory.

Looking past the Omicron wave, the US strategy to manage the epidemic needs to address three issues. First, we should prepare for the emergence of new variants with enough immune escape to lead to a new surge. This includes maintaining surveillance, expanding production and access to antivirals, continuing to promote vaccination among the hesitant, exploring the development of vaccines that can block transmission (as opposed to our current vaccines that primarily reduce severe disease and death), and developing clear messaging for the vulnerable (older and those with comorbidities) to protect themselves through masking and social distancing if a severe variant emerges. Second, as the Omicron wave subsides, accelerate the transition for schools, workplaces, and communities to a more normal life. Nimble responses to future waves of the pandemic will benefit from not prolonging the transition out of the current phase. Third, there will very likely be a winter surge of Omicron or some other variant due to waning immunity and winter seasonality. Hospitals will likely face a double pressure of influenza and winter COVID-19. Planning for how hospitals will manage this increased demand in terms of staff, physical infrastructure, and financing should begin well in advance of the winter.
Current situation

- Estimated daily infections in the last week decreased to 1.8 million per day on average compared to 2.6 million the week before (Figure 1.1).
- Daily hospital census in the last week (through January 31) decreased to 151,000 per day on average compared to 169,400 the week before.
- Daily reported cases in the last week decreased to 465,900 per day on average compared to 659,900 the week before (Figure 2.1).
- Reported deaths due to COVID-19 in the last week increased to 2,400 per day on average compared to 2,200 the week before (Figure 3.1).
- Total deaths due to COVID-19 in the last week increased to 2,800 per day on average compared to 2,600 the week before (Figure 3.1). This makes COVID-19 the number 1 cause of death in US this week (Table 1). Estimated total daily deaths due to COVID-19 in the past week were 1.2 times larger than the reported number of deaths.
- The daily rate of reported deaths due to COVID-19 is greater than 4 per million in 45 states (Figure 4.1).
- The daily rate of total COVID-19 deaths is greater than 4 per million in 48 states (Figure 4.2).
- We estimate that 72% of people in US have been infected at least once as of January 31 (Figure 6.1).
- Effective R, computed using cases, hospitalizations, and deaths, is greater than 1 in Maine and Montana (Figure 7.1).
- The infection-detection rate in US was close to 13% on January 31 (Figure 8.1).
- Based on the GISAID and various national databases, combined with our variant spread model, we estimate the current prevalence of variants of concern (Figure 9.1-Figure 9.5). Omicron is the dominant variant in all states.

Trends in drivers of transmission

- Eight states continue to have mask mandates. Four states have some form of gathering restrictions (Table 1).
- Mobility last week dropped compared to pre-winter holiday levels and was 16% lower than the pre-COVID-19 baseline (Figure 11.1). Mobility was lower than 30% of baseline in no locations.
- As of January 31, in the COVID-19 Trends and Impact Survey, 50% of people self-report that they always wore a mask up from below 40% when the Omicron wave began (Figure 13.1).
- There were 629 diagnostic tests per 100,000 people on January 31 (Figure 15.1).
• As of January 31, 28 states have reached 70% or more of the population who have received at least one vaccine dose, and 16 states have reached 70% or more of the population who are fully vaccinated (Figure 17.1). 75% of people in US have received at least one vaccine dose, and 66% are fully vaccinated. Three states have less than 50% of the population fully vaccinated: Idaho, Wyoming, and Alabama.

• In the US, 81.4% of the population that is 12 years and older say they would accept or would probably accept a vaccine for COVID-19. Note that vaccine acceptance is calculated using survey data from the 18+ population. This is up by 0.4 percentage points from last week. The proportion of the population who are open to receiving a COVID-19 vaccine ranges from 64% in Mississippi to 99% in Massachusetts (Figure 19.1).

• In our current reference scenario, we expect that 246.8 million people will be vaccinated with at least one dose by June 1 (Figure 20.1). We expect that 71% of the population will be fully vaccinated by June 1.

Projections

Infections

• Daily estimated infections in the reference scenario, which represents what we think is most likely to happen, have peaked and should decline steadily reaching below 100,000 a day in April (Figure 21.1).

• Daily estimated infections in the 80% mask coverage scenario decline somewhat faster than in the reference scenario (Figure 21.1).

• Daily estimated infections in the third dose scenario decline somewhat faster than in the reference scenario (Figure 21.1).

Cases

• Daily cases in the reference scenario have peaked and decline steadily reaching pre-Omicron levels by early March (Figure 21.2).

• Daily cases in the 80% mask coverage scenario decline slightly faster than in the reference scenario (Figure 21.2).

• Daily cases in the third dose scenario decline somewhat faster than in the reference scenario (Figure 21.2).

Hospitalizations

• Daily hospital census in the reference scenario has peaked and declines steadily in February and March, reaching pre-Omicron levels in March (Figure 21.3).

• Daily hospital census in the 80% mask coverage scenario decline more rapidly than in the reference scenario (Figure 21.3).

• Daily hospital census in the third dose scenario decline more rapidly than in the reference scenario (Figure 21.3).
Deaths

- In our reference scenario, our model projects 935,000 cumulative reported deaths due to COVID-19 on June 1. This represents 49,000 additional deaths from January 31 to June 1. Daily reported COVID-19 deaths in the reference scenario should peak in the beginning of February and then steadily decline (Figure 21.4).

- Under our reference scenario, our model projects 1,084,000 cumulative total deaths due to COVID-19 on June 1. This represents 58,000 additional deaths from January 31 to June 1 (Figure 24.2).

- In our 80% mask coverage scenario, our model projects 930,000 cumulative reported deaths due to COVID-19 on June 1. This represents 45,000 additional deaths from January 31 to June 1. (Figure 21.4).

- In our third dose scenario, our model projects 934,000 cumulative reported deaths due to COVID-19 on June 1. This represents 49,000 additional deaths from January 31 to June 1. (Figure 21.4).

- Figure 22.1 compares our reference scenario forecasts to other publicly archived models. All models project a peak in February, except the Imperial model that rises to more than 4,000 deaths a day in mid-March.

- At some point from January through June 1, 45 states will have high or extreme stress on hospital beds (Figure 23.1). At some point from January through June 1, 47 states will have high or extreme stress on intensive care unit (ICU) capacity (Figure 24.1).
Model updates

We initially estimated infection-fatality rate (IFR) and infection-hospitalization rate (IHR) of the Omicron variant as reductions relative to the Delta variant based on early evidence from South Africa. In previous weeks, we said the risk of death from an Omicron infection was 0.011 U[0.006, 0.017] relative to a Delta infection, and the relative risk of hospitalization was 0.076 U[0.038, 0.114]. Now that many other locations have peaked and started to decline, we have revised these estimates up to 0.023 U[0.017, 0.028] for the relative risk of death and 0.114 U[0.086, 0.143] for the relative risk of hospitalization. Additionally, we have increased our estimate of the symptomatic fraction of Omicron infections from 10–20% to 15–25%. This results in a higher infection-detection rate (IDR) in the Omicron wave. These adjustments both better reflect our current understanding of the fraction of the population susceptible to an Omicron infection in the last three months, and increase the coherence of our case-based, death-based, and admission-based estimates of transmission intensity.

We also increased the sensitivity of our model to more recent trends in transmission in locations. The model uses deviation of observed transmission from that expected based on covariates and model parameters to calibrate forecasts – lower than expected transmission would decrease forecasted transmission, and greater than expected would increase it. We previously evaluated this over the window of 7 days in the past to 42 days, but in order to be more sensitive to the speed at which Omicron invades, we have adjusted that window to be 2 to 28 days. We also previously made the model more sensitive to underestimates of transmission intensity than to overestimates of transmission intensity. This asymmetric sensitivity matched the Delta-driven period of the pandemic well but produces unrealistic second infection waves in the current Omicron-driven phase. As a result, we have changed this sensitivity to make the model equally responsive to overestimates of transmission intensity as it is to underestimates.

Figure 6.1. Estimated percent of the population infected with COVID-19 on January 31, 2022

Figure 7.1. Mean effective R on January 20, 2022. Effective R less than 1 means that transmission should decline, all other things being held the same. The estimate of effective R is based on the combined analysis of deaths, case reporting, and hospitalizations where available. Current reported cases reflect infections 11-13 days prior, so estimates of effective R can only be made for the recent past.
Figure 8.1. Percent of estimated COVID-19 infections detected. This is estimated as the ratio of reported daily COVID-19 cases to estimated daily COVID-19 infections based on the SEIR disease transmission model. Due to measurement errors in cases and testing rates, the infection-detection rate can exceed 100% at particular points in time.

Figure 20.1. Percent of people who receive at least one dose of a COVID-19 vaccine and those who are fully vaccinated
Projections and scenarios

We produce 3 scenarios when projecting COVID-19. The **reference scenario** is our forecast of what we think is most likely to happen:

- Vaccines are distributed at the expected pace. Brand- and variant-specific vaccine efficacy is updated using the latest available information from peer-reviewed publications and other reports.
- Future mask use is the mean of mask use over the last 7 days.
- Mobility increases as vaccine coverage increases.
- Omicron variant spreads according to our flight and local spread model.

- 80% of those who have had two doses of vaccine (or one dose for Johnson & Johnson) receive a third dose at 6 months after their second dose.

The **80% mask use scenario** makes all the same assumptions as the reference scenario but assumes all locations reach 80% mask use within 7 days. If a location currently has higher than 80% use, mask use remains at the current level.

The **third dose scenario** is the same as the reference scenario but assumes that 100% of those who have received two doses of vaccine will get a third dose at 6 months.
Figure 21.1. Daily COVID-19 infections until June 01, 2022 for 3 scenarios

Figure 21.3. Daily COVID-19 hospital census until June 01, 2022 for 3 scenarios

Figure 21.4 Reported daily COVID-19 deaths per 100,000
Figure 21.5 Total daily COVID-19 deaths per 100,000
**Figure 22.1.** Comparison of reference model projections with other COVID modeling groups. For this comparison, we are including projections of daily COVID-19 deaths from other modeling groups when available, last model update in brackets: Delphi from the Massachusetts Institute of Technology (Delphi) [February 4, 2022], Imperial College London (Imperial) [January 2, 2022], the SI-KJalpha model from the University of Southern California (SIKJalpha) [February 4, 2022], and the CDC Ensemble Model (CDC) [January 31, 2022]. Daily deaths from other modeling groups are smoothed to remove inconsistencies with rounding. Regional values are aggregates from available locations in that region.
Figure 23.1. The estimated inpatient hospital usage is shown over time. The percent of hospital beds occupied by COVID-19 patients is color-coded based on observed quantiles of the maximum proportion of beds occupied by COVID-19 patients. Less than 5% is considered low stress, 5-9% is considered moderate stress, 10-19% is considered high stress, and 20% or greater is considered extreme stress.
**Figure 24.1.** The estimated intensive care unit (ICU) usage is shown over time. The percent of ICU beds occupied by COVID-19 patients is color-coded based on observed quantiles of the maximum proportion of ICU beds occupied by COVID-19 patients. Less than 10% is considered **low stress**, 10-29% is considered **moderate stress**, 30-59% is considered **high stress**, and 60% or greater is considered **extreme stress**.
More information

Data sources:
Mask use and vaccine confidence data are from the The Delphi Group at Carnegie Mellon University and University of Maryland COVID-19 Trends and Impact Surveys, in partnership with Facebook. Mask use data are also from Premise, the Kaiser Family Foundation, and the YouGov COVID-19 Behaviour Tracker survey.

Genetic sequence and metadata are primarily from the GISAID Initiative. Further details available on the COVID-19 model FAQ page.

A note of thanks:
We wish to warmly acknowledge the support of these and others who have made our COVID-19 estimation efforts possible.
