COVID-19 Results Briefing

Thailand

November 18, 2021

This document contains summary information on the latest projections from the IHME model on COVID-19 in Thailand. The model was run on November 16, 2021, with data through November 15, 2021.

Current situation

- Daily infections in the last week increased to 46,000 per day on average compared to 45,200 the week before (Figure 1.1). Daily hospital census in the last week (through November 15) decreased to 7,700 per day on average compared to 8,100 the week before.
- Daily reported cases in the last week decreased to 7,000 per day on average compared to 7,200 the week before (Figure 2.1).
- Reported deaths due to COVID-19 in the last week decreased to 55 per day on average compared to 56 the week before (Figure 3.1).
- Total deaths due to COVID-19 in the last week decreased to 150 per day on average compared to 150 the week before (Figure 3.1). This makes COVID-19 the number 1 cause of death in Thailand this week (Table 1). Estimated total daily deaths due to COVID-19 in the past week were 2.8 times larger than the reported number of deaths.
- No locations had daily reported COVID-19 death rates greater than 4 per million (Figure 4.1).
- No locations had daily total COVID-19 death rates greater than 4 per million (Figure 4.2).
- We estimate that 18% of people in Thailand have been infected as of November 15 (Figure 6.1).
- Effective R, computed using cases, hospitalizations, and deaths, is greater than 1 in 19 locations. Effective R in Thailand was 1 on November 4 (Figure 7.1).
- The infection-detection rate in Thailand was close to 17% on November 15 (Figure 8.1).
- Based on the GISAID and various national databases, combined with our variant spread model, we estimate the current prevalence of variants of concern (Figure 9.1). We estimate that the Beta variant is circulating in 2 countries, that the Delta variant is circulating in 10 countries, and that the Gamma variant is circulating in 1 country in the region.

Trends in drivers of transmission

- Mobility last week was 9% lower than the pre-COVID-19 baseline (Figure 11.1). Mobility was near baseline (within 10%) in Bangladesh, Bhutan, Democratic People’s Republic of Korea, Indonesia, Nepal, and Thailand. Mobility was lower than 30% of baseline in Myanmar, and Sri Lanka.
- As of November 15, in the COVID-19 Trends and Impact Survey, 84% of people self-report that they always wore a mask when leaving their home compared to 84% last week (Figure 13.1).
- There were 71 diagnostic tests per 100,000 people on November 15 (Figure 15.1).
- As of November 15, 3 countries have reached 70% or more of the population who have received at least one vaccine dose and 2 countries have reached 70% or more of the population who are fully vaccinated (Figure 17.1).
- In our current reference scenario, we expect that 55.4 million people will be vaccinated with at least one dose by March 1 (Figure 20.1). We expect that 75% of the population will be fully vaccinated by March 1.
- Based on the estimate of the population that have been infected with COVID-19 and vaccinated to date, combined with assumptions on protection against infection with the Delta variant provided by either natural infection, vaccination or both, we estimate that 36% of the region is immune to the Delta variant. In our current reference scenario, we expect that by March 1, 50% of people will be immune to the Delta variant (Figure 21.1). These two calculations do not take into account waning of natural or vaccine-derived immunity.
Projections

- In our reference scenario, which represents what we think is most likely to happen, our model projects 27,000 cumulative reported deaths due to COVID-19 on March 1. This represents 7,000 additional deaths from November 15 to March 1. Daily reported deaths will rise to 70 by January 3, 2022 (Figure 22.1).

- Under our reference scenario, our model projects 74,000 cumulative total deaths due to COVID-19 on March 1. This represents 19,000 additional deaths from November 15 to March 1 (Figure 22.1).

- If universal mask coverage (95%) were attained in the next week, our model projects 1,200 fewer cumulative reported deaths compared to the reference scenario on March 1.

- Under our worse scenario, our model projects 48,000 cumulative reported deaths on March 1, an additional 21,000 deaths compared to our reference scenario. Daily reported deaths in the worse scenario will rise to 530 by February 2, 2022 (Figure 22.1).

- Daily infections in the reference scenario will rise to 50,730 by December 9, 2021 (Figure 22.3). Daily infections in the worse scenario will rise to 375,750 by January 8, 2022 (Figure 22.3).

- Daily cases in the reference scenario will rise to 8,930 by December 21, 2021 (Figure 22.4). Daily cases in the worse scenario will rise to 67,430 by January 19, 2022 (Figure 22.4).

- Daily hospital census in the reference scenario will rise to 8,190 by December 25, 2021 (Figure 22.5). Daily hospital census in the worse scenario will rise to 58,030 by January 26, 2022 (Figure 22.5).

- Figure 23.1 compares our reference scenario forecasts to other publicly archived models. Forecasts are widely divergent.

- At some point from November through March 1, 2 countries will have high or extreme stress on hospital beds (Figure 24.1). At some point from November through March 1, 5 countries will have high or extreme stress on intensive care unit (ICU) capacity (Figure 25.1).

Figure 7.1. Mean effective R on November 4, 2021. Effective R less than 1 means that transmission should decline, all other things being held the same. The estimate of effective R is based on the combined analysis of deaths, case reporting, and hospitalizations where available. Current reported cases reflect infections 11-13 days prior, so estimates of effective R can only be made for the recent past.
**Figure 8.1.** Percent of COVID-19 infections detected. This is estimated as the ratio of reported daily COVID-19 cases to estimated daily COVID-19 infections based on the SEIR disease transmission model. Due to measurement errors in cases and testing rates, the infection-detection rate can exceed 100% at particular points in time.

Table 3. Estimates of vaccine efficacy for specific vaccines used in the model at preventing disease and infection. The SEIR model uses variant-specific estimates of vaccine efficacy at preventing symptomatic disease and at preventing infection. We use data from clinical trials directly, where available, and make estimates otherwise. More information can be found on our website.

Projections and scenarios

We produce three scenarios when projecting COVID-19. The reference scenario is our forecast of what we think is most likely to happen:

- Vaccines are distributed at the expected pace. Brand- and variant-specific vaccine efficacy is updated using the latest available information from peer-reviewed publications and other reports.
- Future mask use is the mean of mask use over the last 7 days.
- Mobility increases as vaccine coverage increases.
- Governments adapt their response by re-imposing social distancing mandates for 6 weeks whenever daily deaths reach 8 per million, unless a location has already spent at least 7 of the last 14 days with daily deaths above this rate, and not yet re-imposed social distancing mandates. In this case, the reference scenario assumes that mandates are re-imposed when daily deaths reach 15 per million.
- Variants Alpha, Beta, Gamma, and Delta continue to spread regionally and globally from locations with sufficient transmission.

The worse scenario modifies the reference scenario assumption in four ways:

- 100% of vaccinated individuals stop using masks.
- Mobility increases in all locations to 25% above the pre-pandemic winter baseline, irrespective of vaccine coverage.
- Governments are more reluctant to re-impose social distancing mandates, waiting until the daily death rate reaches 15 per million, unless a location has already spent at least 7 of the last 14 days with daily deaths above this rate, and not yet re-imposed social distancing mandates. In this case, the reference scenario assumes that mandates are re-imposed when daily deaths reach 38 per million. In either case, we assume social distancing mandates remain in effect for 6 weeks.
- Variants Alpha, Beta, Gamma, and Delta spread between locations twice as fast when compared with our reference scenario.

The universal masks scenario makes all the same assumptions as the reference scenario but assumes all locations reach 95% mask use within 7 days.
Daily COVID-19 deaths until March 01, 2022 for three scenarios

Figure 22.1 Reported daily COVID-19 deaths per 100,000

Figure 22.2 Total daily COVID-19 deaths per 100,000
Figure 22.3. Daily COVID-19 infections until March 01, 2022 for three scenarios

Figure 22.4. Daily COVID-19 reported cases until March 01, 2022 for three scenarios
Figure 22.5. Daily COVID-19 hospital census until March 01, 2022 for three scenarios
Figure 23.1. Comparison of reference model projections with other COVID modeling groups. For this comparison, we are including projections of daily COVID-19 deaths from other modeling groups when available, last model update in brackets: Delphi from the Massachusetts Institute of Technology (Delphi) [November 17, 2021], Imperial College London (Imperial) [November 3, 2021], the SI-KJalpha model from the University of Southern California (SIKJalpha) [November 17, 2021]. Daily deaths from other modeling groups are smoothed to remove inconsistencies with rounding. Regional values are aggregates from available locations in that region.
Figure 24.1. The estimated inpatient hospital usage is shown over time. The percent of hospital beds occupied by COVID-19 patients is color-coded based on observed quantiles of the maximum proportion of beds occupied by COVID-19 patients. Less than 5% is considered low stress, 5-9% is considered moderate stress, 10-19% is considered high stress, and 20% or greater is considered extreme stress.
Figure 25.1. The estimated intensive care unit (ICU) usage is shown over time. The percent of ICU beds occupied by COVID-19 patients is color-coded based on observed quantiles of the maximum proportion of ICU beds occupied by COVID-19 patients. Less than 10% is considered low stress, 10-29% is considered moderate stress, 30-59% is considered high stress, and 60% or greater is considered extreme stress.
More information

Data sources:
Mask use and vaccine confidence data are from the The Delphi Group at Carnegie Mellon University and University of Maryland COVID-19 Trends and Impact Surveys, in partnership with Facebook. Mask use data are also from Premise, the Kaiser Family Foundation, and the YouGov COVID-19 Behaviour Tracker survey.
Genetic sequence and metadata are primarily from the GISAID Initiative. Further details available on the COVID-19 model FAQ page.

A note of thanks:
We wish to warmly acknowledge the support of these and others who have made our COVID-19 estimation efforts possible.
