COVID-19 Results Briefing
Viet Nam
June 13, 2022

This document contains summary information on the latest projections from the IHME model on COVID-19 in Viet Nam. The model was run on June 8, 2022, with data through June 6, 2022.

Current situation

- Daily infections in the last week decreased to 4,600 per day on average compared to 6,000 the week before (Figure 1.1). Daily hospital census in the last week (through June 6) decreased to 110 per day on average compared to 160 the week before.
- Daily reported cases in the last week decreased to 1,100 per day on average compared to 1,300 the week before (Figure 2.1).
- Reported deaths due to COVID-19 in the last week remained the same at zero per day on average compared to the week before (Figure 3.1).
- Total deaths due to COVID-19 in the last week remained the same at one per day on average compared to the week before (Figure 3.1). This makes COVID-19 the number 89 cause of death in Viet Nam this week (Table 1). Estimated total daily deaths due to COVID-19 in the past week were 1.9 times larger than the reported number of deaths.
- The daily rate of reported deaths due to COVID-19 is greater than 4 per million in no countries (Figure 4.1).
- The daily rate of total deaths due to COVID-19 is greater than 4 per million in no countries (Figure 4.2).
- We estimate that 67% of people in Viet Nam have been infected at least once as of June 6 (Figure 6.1). Effective R, computed using cases, hospitalizations, and deaths, is greater than 1 in seven countries and five subnational locations. Effective R in Viet Nam was 0.8 on May 26 (Figure 7.1).
- The infection-detection rate in Viet Nam was close to 20% on June 6 (Figure 8.1).
- Based on the GISAID and various national databases, combined with our variant spread model, we estimate the current prevalence of variants of concern (Figures 9.1-9.5). We estimate that the Alpha variant is circulating in eight countries and no subnational locations, that the Beta variant is circulating in six countries and no subnational locations, that the Delta variant is circulating in 15 countries and three subnational locations, that the Gamma variant is circulating in three countries and no subnational locations, and that the Omicron variant is circulating in 15 countries and 31 subnational locations.

Trends in drivers of transmission

- Mobility last week was 22% lower than the pre-COVID-19 baseline (Figure 11.1). Mobility was lower than 15% of baseline in two countries (Figure 12.1).
- As of May 29, in the COVID-19 Trends and Impact Survey, 54% of people self-reported that they always wore a mask when leaving their home compared to 55% the previous week (Figure 13.1).
- There were 43 diagnostic tests per 100,000 people on June 6 (Figure 15.1).
- As of June 6, 19 countries and 33 subnational locations have reached 70% or more of the population who have received at least one vaccine dose, and 14 countries and 32 subnational locations have reached 70% or more of the population who are fully vaccinated (Figures 17.1 and 17.2). 88% of people in Viet Nam have received at least one vaccine dose, and 83% are fully vaccinated.
- In Viet Nam, 99.3% of the population that is 12 years and older say they would accept a vaccine for COVID-19 (Figure 18.1). This is the same as the previous week. In Viet Nam, 99.3% of the population that is 12 years and older say they would accept a vaccine for COVID-19 (Figure 18.1). This is the same as the previous week. The proportion of the population who are open to receiving a COVID-19
vaccine ranges from 47% in Papua New Guinea to 100% in Lao People’s Democratic Republic (Figure 19.1). Note that vaccine acceptance is calculated using survey data from the 18+ population.

- As of May 30, 2022, zero percent of the population in Viet Nam say they would accept a vaccine for COVID-19 but have not yet been vaccinated.
- In our current reference scenario, we expect that 88.5 million people will be vaccinated with at least one dose by October 1 (Figure 21.1). We expect that 86% of the population will be fully vaccinated by October 1.

Projections and scenarios

We produce three scenarios when projecting COVID-19. The reference scenario is our forecast of what we think is most likely to happen:

- Vaccines are distributed at the expected pace. Brand- and variant-specific vaccine efficacy is updated using the latest available information from peer-reviewed publications and other reports.
- Future mask use will decline to 50% of the minimum level it reached between January 1, 2021, and May 1, 2022. This decline begins after the last observed data point in each location and transitions linearly to the minimum over a period of six weeks.
- Mobility increases as vaccine coverage increases.
- 80% of those who have had two doses of vaccine (or one dose for Johnson & Johnson) receive a third dose at six months after their second dose.
- Antiviral utilization for COVID-19 risk prevention in high-risk populations will reach 80% between June 15, 2022, and July 31, 2022. This applies in high-income countries, but not low- and middle-income countries, and this rollout assumption follows a similar pattern to global vaccine rollouts.

The 80% mask use scenario makes all the same assumptions as the reference scenario but assumes all locations reach 80% mask use within seven days. If a location currently has higher than 80% use, mask use remains at the current level.

The antiviral access scenario makes all the same assumptions as the reference scenario but assumes globally distributed antivirals and extends coverage to all low- and middle-income countries between August 15, 2022, and September 30, 2022.

Infections

- Daily estimated infections in the reference scenario will decline to 550 by August 14, 2022 (Figure 23.1).
- Daily estimated infections in the 80% mask use scenario will decline to 60 by September 1, 2022 (Figure 23.1).
- Daily estimated infections in the antiviral access scenario will decline to 550 by August 14, 2022 (Figure 23.1).

Cases

- Daily estimated cases in the reference scenario will decline to 70 by September 4, 2022 (Figure 23.2).
- Daily estimated cases in the 80% mask use scenario will decline to 10 by September 22, 2022 (Figure 23.2).
- Daily estimated cases in the antiviral access scenario will decline to 70 by September 4, 2022 (Figure 23.2).

Hospitalizations

- Daily hospital census in the reference scenario will decline to 10 by September 1, 2022 (Figure 23.3). At some point from June through October 1, no countries will have high or extreme stress on hospital beds (Figure 25.1). At some point from June through October 1, three countries will have high or extreme stress on intensive care unit (ICU) capacity (Figure 26.1).
• Daily hospital census in the 80% mask use scenario will decline to zero by September 19, 2022 (Figure 23.3).
• Daily hospital census in the antiviral access scenario will decline to 10 by September 9, 2022 (Figure 23.3).

Deaths

• In our reference scenario, our model projects 43,000 cumulative reported deaths due to COVID-19 on October 1. This represents 22 additional deaths from June 6 to October 1. Daily reported COVID-19 deaths in the reference scenario will rise to zero by June 19, 2022 (Figure 23.4).
• Under our reference scenario, our model projects 83,000 cumulative total deaths due to COVID-19 on October 1. This represents 42 additional deaths from June 6 to October 1 (Figure 23.5).
• In our 80% mask use scenario, our model projects 43,000 cumulative reported deaths due to COVID-19 on October 1. This represents 16 additional deaths from June 6 to October 1. Daily reported COVID-19 deaths in the 80% mask use scenario will rise to zero by June 19, 2022 (Figure 23.4).
• In our antiviral access scenario, our model projects 43,000 cumulative reported deaths due to COVID-19 on October 1. This represents 22 additional deaths from June 6 to October 1. Daily reported COVID-19 deaths in the antiviral access scenario will rise to zero by June 19, 2022 (Figure 23.4).
• Figure 24.1 compares our reference scenario forecasts to other publicly archived models. Forecasts are widely divergent.
Model updates

This month, we have made three alterations to our reference assumptions in the model. First, we expect the recent rollout of Paxlovid treatments in high-income settings to greatly reduce severe disease and death outcomes. We do not currently have data to inform levels of coverage, so we have introduced a simple scale-up model that assumes individuals over the age of 65 will be targeted for treatment, and access to treatment among this group will rise from 0% on June 15, 2022, to a maximum of 80% on July 31, 2022. Clinical trials suggest a Paxlovid provides an 88% reduction in the risk of hospitalization and death https://www.pfizer.com/news/press-release/press-release-detail/pfizer-announces-additional-phase-23-study-results among people treated within five days of symptom onset. We make a slightly more conservative assumption that the hospitalization and death rates will be reduced by 80% to account for variations in treatment timing and patient adherence in a real-world setting.

Second, survey data suggest that mask use is continuing to decline in most world locations. We have updated our reference mask use forecast to introduce a linear decline in mask use prevalence down to 50% of the minimum use level between January 1, 2021, and May 1, 2022, in each location. We have kept our previous assumption that mask use will continue at current levels in China, South Korea, Japan, Taiwan, Singapore, and South Africa, as current data do not suggest an imminent reduction.

Finally, similar to mask use, observed mobility continues to increase in much of the world. We have replaced our previous reference scenario that assumed current levels of mobility would persist indefinitely with a scenario that has mobility increase to match vaccine coverage. We continue to produce three scenarios when projecting COVID-19, but we have replaced the increased booster coverage scenario with an antiviral access scenario that examines the impact of more equitable distribution of Paxlovid to low- and middle-income countries (LMICs).

Figure 6.1: Estimated percent of the population infected with COVID-19 on June 6, 2022.

Figure 7.1: Mean effective R on May 26, 2022. Effective R less than 1 means that transmission should decline, all other things being held the same. The estimate of effective R is based on the combined analysis of deaths, case reporting, and hospitalizations where available. Current reported cases reflect infections 11-13 days prior, so estimates of effective R can only be made for the recent past.
Figure 8.1: Percent of estimated COVID-19 infections detected. This is estimated as the ratio of reported daily COVID-19 cases to estimated daily COVID-19 infections based on the SEIR disease transmission model. Due to measurement errors in cases and testing rates, the infection-detection rate can exceed 100% at particular points in time.

More information

Data sources:
Mask use and vaccine confidence data are from the The Delphi Group at Carnegie Mellon University and University of Maryland COVID-19 Trends and Impact Surveys, in partnership with Facebook. Mask use data are also from Premise, the Kaiser Family Foundation, and the YouGov COVID-19 Behaviour Tracker survey.

Genetic sequence and metadata are primarily from the GISAID Initiative. Further details available on the COVID-19 model FAQ page.

A note of thanks:
We wish to warmly acknowledge the support of these and others who have made our COVID-19 estimation efforts possible.
