COVID-19 Results Briefing

Greece

December 22, 2021

This document contains summary information on the latest projections from the IHME model on COVID-19 in Greece. The model was run on December 21, 2021, with data through December 13, 2021.

Current situation

- Daily infections in the last week increased to 6,800 per day on average compared to 6,400 the week before (Figure 1.1). Daily hospital census in the last week (through December 13) decreased to 720 per day on average compared to 770 the week before.
- Daily reported cases in the last week decreased to 5,200 per day on average compared to 5,700 the week before (Figure 2.1).
- Reported deaths due to COVID-19 in the last week decreased to 88 per day on average compared to 93 the week before (Figure 3.1).
- Total deaths due to COVID-19 in the last week decreased to 88 per day on average compared to 93 the week before (Figure 3.1). This makes COVID-19 the number 1 cause of death in Greece this week (Table 1). Estimated total daily deaths due to COVID-19 in the past week were 1 times larger than the reported number of deaths.
- The daily rate of reported deaths due to COVID-19 is greater than 4 per million in 21 countries and no subnationals. (Figure 4.1)
- The daily rate of reported deaths due to COVID-19 is greater than 4 per million in 31 countries and no subnationals. (Figure 4.2)
- We estimate that 18% of people in Greece have been infected at least once as of December 13 (Figure 6.1). Effective R, computed using cases, hospitalizations, and deaths, is greater than 1 in 36 countries and 60 subnational locations in the region. Effective R in Greece was 0.9 on December 2 (Figure 7.1).
- The infection-detection rate in Greece was close to 78% on December 13 (Figure 8.1).
- Based on the GISAID and various national databases, combined with our variant spread model, we estimate the current prevalence of variants of concern (Figure 9.1-Figure 9.5). We estimate that the Alpha variant is circulating in one country and 0 subnational locations, that the Beta variant is circulating in 0 countries and 0 subnational locations, that the Delta variant is circulating in 48 countries and 0 subnational locations, that the Gamma variant is circulating in 2 countries and 0 subnational locations and that the Omicron variant is circulating in 46 countries and 0 subnational locations.

Trends in drivers of transmission

---

---
In our current reference scenario, we expect that 7.2 million people will be vaccinated with at least one dose by April 1 (Figure 20.1). We expect that 66% of the population will be fully vaccinated by April 1.

Projections

Infections

- Daily estimated infections in the reference scenario, which represents what we think is most likely to happen, will rise to 46,230 by February 16, 2022 (Figure 21.1).
- Daily estimated infections in the high severity of Omicron scenario will rise to 45,070 by February 14, 2022 (Figure 21.1).
- Daily estimated infections in the 80% mask coverage scenario will rise to 30,920 by February 21, 2022 (Figure 21.1).
- Daily estimated infections in the third dose scenario will rise to 43,360 by February 15, 2022 (Figure 21.1).
- Daily estimated infections in the reduced vaccine hesitancy scenario will rise to 46,060 by February 16, 2022 (Figure 21.1).

Cases

- Daily cases in the reference scenario will rise to 21,940 by March 1, 2022 (Figure 21.2).
- Daily cases in the high severity of Omicron scenario will rise to 21,060 by February 28, 2022 (Figure 21.2).
- Daily cases in the 80% mask coverage scenario will rise to 14,480 by March 5, 2022 (Figure 21.2).
- Daily cases in the third dose scenario will rise to 20,530 by February 28, 2022 (Figure 21.2).
- Daily cases in the reduced vaccine hesitancy scenario will rise to 21,850 by March 1, 2022 (Figure 21.2).

Hospitalizations

- Daily hospital census in the reference scenario will rise to 700 by March 8, 2022 (Figure 21.3).
- Daily hospital census in the high severity of Omicron scenario will rise to 1,040 by March 11, 2022 (Figure 21.3).
- Daily hospital census in the 80% mask coverage scenario will decline to 370 on April 1, 2022 (Figure 21.3).
- Daily hospital census in the third dose scenario will decline to 470 by January 16, 2022 (Figure 21.3).
- Daily hospital census in the reduced vaccine hesitancy scenario will rise to 670 by March 8, 2022 (Figure 21.3).

Deaths

- In our reference scenario, our model projects 24,000 cumulative reported deaths due to COVID-19 on April 1. This represents 5,000 additional deaths from December 13 to April 1. Daily reported COVID-19 deaths in the reference scenario will decline to 30 on April 1, 2022 (Figure 21.4).
- Under our reference scenario, our model projects 24,000 cumulative total deaths due to COVID-19 on April 1. This represents 5,000 additional deaths from December 13 to April 1 (Figure 24.2).
- In our high severity of Omicron scenario, our model projects 25,000 cumulative reported deaths due to COVID-19 on April 1. This represents 6,000 additional deaths from December 13 to April 1. Daily reported COVID-19 deaths in the high severity of Omicron scenario will decline to 40 by January 13, 2022 (Figure 21.4).
- In our 80% mask coverage scenario, our model projects 23,000 cumulative reported deaths due to COVID-19 on April 1. This represents 4,000 additional deaths from December 13 to April 1. Daily reported COVID-19 deaths in the 80% mask coverage scenario will decline to 20 on April 1, 2022 (Figure 21.4).
• In our **third dose scenario**, our model projects 24,000 cumulative reported deaths due to COVID-19 on April 1. This represents 5,000 additional deaths from December 13 to April 1. Daily reported COVID-19 deaths in the **third dose scenario** will decline to 30 on April 1, 2022 (Figure 21.4).

• In our **reduced vaccine hesitancy scenario**, our model projects 24,000 cumulative reported deaths due to COVID-19 on April 1. This represents 4,000 additional deaths from December 13 to April 1. Daily reported COVID-19 deaths in the **reduced vaccine hesitancy scenario** will decline to 30 on April 1, 2022 (Figure 21.4).

• Figure 22.1 compares our reference scenario forecasts to other publicly archived models. Forecasts are widely divergent.

• At some point from December through April 1, 2 countries will have high or extreme stress on hospital beds (Figure 23.1). At some point from December through April 1, 27 countries will have high or extreme stress on intensive care unit (ICU) capacity (Figure 24.1).
Model updates

In this update, we have substantially revised our model to explicitly account for several important factors that have a profound influence on the likely trajectory of the epidemic in the coming months. First, the model tracks infections from different variants separately, including ancestral, Alpha, Beta, Gamma, Delta, Omicron, and other. Second, we take into account that infection-derived and vaccine-derived immunity wanes over time. Immunity that prevents infection wanes more quickly than immunity preventing hospitalization and death, so we derive separate waning curves for infection and for hospitalization and death. Based on a systematic analysis of published studies, reports, and archived studies, we derive vaccine-specific waning curves. Third, infection with different COVID-19 variants can confer different protection for each variant in the model. The matrix of cross-variant immunity allows us to take into account the greater immune escape seen with Omicron. Third, we explicitly model the delivery of a third dose of vaccine (and second dose for J&J recipients). Fourth, the variant spread model is now based on both spatial spread and patterns of airline traffic. The technical appendix provides details of the model structure and the analysis of waning immunity. The critical driver of our forecasts in the next months is the spread of the Omicron variant. Critical assumptions about the Omicron variant are based on our analysis of all the available lab data on vaccine efficacy, test-negative vaccine effectiveness studies in South Africa and the UK, population-level data on PCR positivity in representative samples of the population, and detected cases, hospitalization, and deaths in South Africa, the UK, Denmark, and Norway. More details on this analysis are in the technical appendix. The key assumptions that substantially influence the forecasts include the following: First, prior infection provides 40% to 60% protection against infection with Omicron. Second, vaccine effectiveness in preventing infection is reduced by approximately 50% compared to the efficacy against the Delta variant, and vaccine effectiveness in preventing hospitalization and death is reduced by 25% compared to the efficacy against the Delta variant. Third, the fraction asymptomatic is assumed to increase from near 40% to 90%-95%; this fraction influences the future estimates of the infection-detection rate. Fourth, the infection-hospitalization rate for Omicron is estimated to be 90%-96% lower than for Delta variant. Fifth, the infection-fatality rate for Omicron is estimated to be 97%-99% lower than for Delta.

Figure 7.1. Mean effective R on December 2, 2021. Effective R less than 1 means that transmission should decline, all other things being held the same. The estimate of effective R is based on the combined analysis of deaths, case reporting, and hospitalizations where available. Current reported cases reflect infections 11-13 days prior, so estimates of effective R can only be made for the recent past.
Figure 8.1. Percent of estimated COVID-19 infections detected. This is estimated as the ratio of reported daily COVID-19 cases to estimated daily COVID-19 infections based on the SEIR disease transmission model. Due to measurement errors in cases and testing rates, the infection-detection rate can exceed 100% at particular points in time.

Figure 20.1. Percent of people who receive at least one dose of a COVID-19 vaccine and those who are fully vaccinated
Projections and scenarios

We produce five scenarios when projecting COVID-19. The reference scenario is our forecast of what we think is most likely to happen:

- Vaccines are distributed at the expected pace. Brand- and variant-specific vaccine efficacy is updated using the latest available information from peer-reviewed publications and other reports.
- Future mask use is the mean of mask use over the last 7 days.
- Mobility increases as vaccine coverage increases.
- Omicron variant spreads according to our flight and local spread model.

- 80% of those who have had two doses of vaccine (or one dose for Johnson & Johnson) receive a third dose at 6 months after their second dose.

The high severity of Omicron scenario modifies the reference scenario assumption in two ways: * The infection-hospitalization ratio for Omicron is 2.3 times as high as compared to the reference scenario. * The infection-fatality rate is 4.6 times as high as compared to the reference scenario.

The 80% mask use scenario makes all the same assumptions as the reference scenario but assumes all locations reach 80% mask use within 7 days. If a location currently has higher than 80% use, mask use remains at the current level.

The third dose scenario is the same as the reference scenario but assumes that 100% of those who have received two doses of vaccine will get a third dose at 6 months.

The reduced vaccine hesitancy scenario assumes that those in each location who respond on surveys that they probably will not receive a vaccine are persuaded or mandated to receive a vaccine.

Figure 24.3. Reported daily COVID-19 deaths per 100,000
Figure 24.4 Total daily COVID-19 deaths per 100,000
Figure 22.1. Comparison of reference model projections with other COVID modeling groups. For this comparison, we are including projections of daily COVID-19 deaths from other modeling groups when available, last model update in brackets: Delphi from the Massachusetts Institute of Technology (Delphi) [December 21, 2021], Imperial College London (Imperial) [December 5, 2021], the SI-KJalpha model from the University of Southern California (SIKJalpha) [December 19, 2021]. Daily deaths from other modeling groups are smoothed to remove inconsistencies with rounding. Regional values are aggregates from available locations in that region.
Figure 23.1. The estimated inpatient hospital usage is shown over time. The percent of hospital beds occupied by COVID-19 patients is color-coded based on observed quantiles of the maximum proportion of beds occupied by COVID-19 patients. Less than 5% is considered low stress, 5-9% is considered moderate stress, 10-19% is considered high stress, and 20% or greater is considered extreme stress.
**Figure 24.1.** The estimated intensive care unit (ICU) usage is shown over time. The percent of ICU beds occupied by COVID-19 patients is color-coded based on observed quantiles of the maximum proportion of ICU beds occupied by COVID-19 patients. Less than 10% is considered *low stress*, 10-29% is considered *moderate stress*, 30-59% is considered *high stress*, and 60% or greater is considered *extreme stress*.
More information

Data sources:
Mask use and vaccine confidence data are from the The Delphi Group at Carnegie Mellon University and University of Maryland COVID-19 Trends and Impact Surveys, in partnership with Facebook. Mask use data are also from Premise, the Kaiser Family Foundation, and the YouGov COVID-19 Behaviour Tracker survey.
Genetic sequence and metadata are primarily from the GISAID Initiative. Further details available on the COVID-19 model FAQ page.

A note of thanks:
We wish to warmly acknowledge the support of these and others who have made our COVID-19 estimation efforts possible.
