COVID-19 Results Briefing

Global

January 21, 2022

This document contains summary information on the latest projections from the IHME model on COVID-19 globally. The model was run on January 20, 2022, with data through January 18, 2022.

The global Omicron wave continues to unfold. The only countries that have not begun their Omicron surge include most of Southeast Asia with the exception of the Philippines, China, New Zealand, Libya, and Slovakia. In this week's update, we model in the reference scenario a national Omicron outbreak in China beginning in February. Multiple countries or states/regions within countries have already peaked and begun to decline. From initial surge in reported cases to the peak, the interval is consistently between 20 and 25 days regardless of vaccination levels or prevalence of past infection. The likely explanation is the extremely high transmissibility of Omicron and considerable immune escape from vaccine-derived and infection-acquired immunity. Perhaps the most important insight is the extraordinary speed of the Omicron wave and the likelihood that nearly all countries will be through the wave by mid-March. The unprecedented level of infection is creating heavy pressure on health systems but fortunately is not leading to a major surge in deaths from COVID-19.

Given what we have learned about the speed and intensity of the Omicron wave, policy interventions appear to have a very limited impact in the short run. In our scenarios, expanding mask use or third-dose vaccination speeds the decline of transmission, but compared to previous variants these effects are quite modest. Testing, tracing, and quarantine are unlikely to have an impact given the volume of infection in most countries. Acutely, the main efforts of governments should focus on supporting health systems that face pressure due to the surge in COVID-19-related admissions, the large number of admissions for other health problems that have incidental COVID-19 infections requiring infection control measures, and the shortages of health workers due to quarantine. Given the rapid wave, governments may want to keep in place existing measures and mandates and consider removing them in a few weeks after transmission drops, just to be cautious.

After the Omicron wave subsides, high levels of infection-acquired and vaccine-derived immunity should lead to low levels of transmission for many weeks or months. In the Northern Hemisphere, further reductions in transmission potential over the summer may extend the period of low COVID-19 infections into later in the year.
COVID-19 will return, however, for two reasons. First, vaccine-derived and infection-derived immunity preventing infection will steadily wane. Waning immunity and winter seasonality later in 2022 should lead at least to a winter increase in the Northern Hemisphere and possibly an earlier return in the Southern Hemisphere winter. Second, new variants are highly likely to emerge. In fact, the billions of global infections occurring in the world from the end of November to March 1 may have created the opportunity for new variants to emerge already. To prepare for future COVID-19 variants, governments should maintain surveillance and monitor for the emergence of new variants, continue to promote vaccination including third doses where vaccines are available, scale up access to effective antivirals, and provide guidance for high-risk groups to use high-quality masks and social distance if and when a new variant that is more severe than Omicron emerges. Accelerating access to antivirals in low- and middle-income countries takes on greater importance. With these measures in place, even the emergence of a new variant with increased severity as compared to Omicron should not require the return to pandemic-era mandates.

Current situation

- Estimated daily infections in the last week increased to 95.2 million per day on average compared to 90.4 million the week before (Figure 1.1).

- Daily hospital census in the last week (through January 18) increased to 1.6 million per day on average compared to 1.1 million the week before.

- Daily reported cases in the last week increased to 3.0 million per day on average compared to 2.6 million the week before (Figure 2.1).

- Reported deaths due to COVID-19 in the last week increased to 7,400 per day on average compared to 7,000 the week before (Figure 3.1).

- Total deaths due to COVID-19 in the last week increased to 13,600 per day on average compared to 12,600 the week before (Figure 3.1). This makes COVID-19 the number 3 cause of death globally this week (Table 1). Estimated total daily deaths due to COVID-19 in the past week were 1.8 times larger than the reported number of deaths.

- The daily rate of reported deaths due to COVID-19 is greater than 4 per million in 28 countries and no subnational locations (Figure 4.1).

- The daily rate of total deaths due to COVID-19 is greater than 4 per million in 58 countries and no subnational locations (Figure 4.2).

- We estimate that 57% of people globally have been infected at least once as of January 18 (Figure 6.1).

- Effective R, computed using cases, hospitalizations, and deaths, is greater than 1 in 110 countries and 136 subnational locations (Figure 7.1). Transmission is declining in much of sub-Saharan Africa, Canada, the eastern and southern USA, Western and Southern Europe, and Australia.

- The infection-detection rate globally was close to 4% on January 18 (Figure 8.1).
Based on the GISAID and various national databases, combined with our variant spread model, we estimate the current prevalence of variants of concern (Figures 9.1–9.5). Omicron is dominant in nearly all countries.

Trends in drivers of transmission

- Mobility last week was 9% higher than the pre-COVID-19 baseline (Figure 11.1). Mobility was lower than 30% of baseline in no locations.
- As of January 18, in the COVID-19 Trends and Impact Survey, 55% of people self-report that they always wore a mask when leaving their home (Figure 13.1).
- There were 176 diagnostic tests per 100,000 people on January 18 (Figure 15.1).
- As of January 18, 70 countries and no subnational locations have reached 70% or more of the population who have received at least one vaccine dose, and 44 countries and no subnational locations have reached 70% or more of the population who are fully vaccinated (Figure 17.1). 61% of people globally have received at least one vaccine dose and 52% are fully vaccinated. First-dose vaccination rates less than 50% are seen in most countries in Africa, parts of Eastern Europe, and select countries in other regions.
- Globally, 68.2% of the population that is 12 years and older say they would accept or would probably accept a vaccine for COVID-19. Note that vaccine acceptance is calculated using survey data from the 18+ population. The proportion of the population who are open to receiving a COVID-19 vaccine ranges from 31% in Namibia to 100% in United Arab Emirates (Figure 19.1).
- In our current reference scenario, we expect that 5.0 billion people will be vaccinated with at least one dose by May 1 (Figure 20.1). We expect that 59% of the population will be fully vaccinated by May 1.

Projections

Infections

- Daily estimated infections in the reference scenario, which represents what we think is most likely to happen, have peaked and will decline to 1.4 million on May 1, 2022 (Figure 21.1).
- Daily estimated infections in the 80% mask coverage scenario decline faster from the peak than in the reference scenario (Figure 21.1).
- Daily estimated infections in the third dose scenario will decline slightly faster than in the reference scenario (Figure 21.1).

Cases

- Daily cases in the reference scenario peak at 3.1 million cases on January 21 and then decline rapidly, reaching below 500,000 by mid-March (Figure 21.2).
- Daily cases in the **80% mask coverage scenario** decline more rapidly than in the reference scenario (Figure 21.2).

- Daily cases in the **third dose scenario** decline more rapidly than in the reference scenario (Figure 21.2).

**Hospitalizations**

- Daily hospital census in the **reference scenario** will rise to 2.3 million by the end of January and then decline (Figure 21.3).

- Daily hospital census in the **80% mask coverage scenario** will rise to 2.2 million in the last week of January and then decline (Figure 21.3).

- Daily hospital census in the **third dose scenario** is similar to the reference scenario but with a slightly faster decline from the peak (Figure 21.3).

**Deaths**

- In our **reference scenario**, our model projects 6,334,000 cumulative reported deaths due to COVID-19 on May 1. This represents 275,000 additional deaths from January 18 to May 1. Daily reported COVID-19 deaths in the **reference scenario** will rise to 7,190 by January 22, 2022, and then decline (Figure 21.4).

- Under our **reference scenario**, our model projects 13,472,000 cumulative total deaths due to COVID-19 on May 1. This represents 613,000 additional deaths from January 18 to May 1 (Figure 24.2).

- In our **80% mask coverage scenario**, our model projects 6,318,000 cumulative reported deaths due to COVID-19 on May 1. This represents 259,000 additional deaths from January 18 to May 1. Daily reported COVID-19 deaths in the **80% mask coverage scenario** will rise to 7,190 by January 22, 2022 (Figure 21.4).

- In our **third dose scenario**, our model projects 6,321,000 cumulative reported deaths due to COVID-19 on May 1. This represents 262,000 additional deaths from January 18 to May 1. Daily reported COVID-19 deaths in the **third dose scenario** will rise to 7,100 by January 21, 2022 (Figure 21.4).

- At some point from January through May 1, 33 countries will have high or extreme stress on hospital beds (Figure 23.1). At some point from January through May 1, 48 countries will have high or extreme stress on intensive care unit (ICU) capacity (Figure 24.1).

Figure 7.1. Mean effective R on January 7, 2022. Effective R less than 1 means that transmission should decline, all other things being held the same. The estimate of effective R is based on the combined analysis of deaths, case reporting, and hospitalizations where available. Current reported cases reflect infections 11-13 days prior, so estimates of effective R can only be made for the recent past.
**Figure 8.1.** Percent of estimated COVID-19 infections detected. This is estimated as the ratio of reported daily COVID-19 cases to estimated daily COVID-19 infections based on the SEIR disease transmission model. Due to measurement errors in cases and testing rates, the infection-detection rate can exceed 100% at particular points in time.

**Figure 20.1.** Percent of people who receive at least one dose of a COVID-19 vaccine and those who are fully vaccinated.
Projections and scenarios

We produce 3 scenarios when projecting COVID-19. The **reference scenario** is our forecast of what we think is most likely to happen:

- Vaccines are distributed at the expected pace. Brand- and variant-specific vaccine efficacy is updated using the latest available information from peer-reviewed publications and other reports.
- Future mask use is the mean of mask use over the last 7 days.
- Mobility increases as vaccine coverage increases.
- Omicron variant spreads according to our flight and local spread model.

- 80% of those who have had two doses of vaccine (or one dose for Johnson & Johnson) receive a third dose at 6 months after their second dose.

The **80% mask use scenario** makes all the same assumptions as the reference scenario but assumes all locations reach 80% mask use within 7 days. If a location currently has higher than 80% use, mask use remains at the current level.

The **third dose scenario** is the same as the reference scenario but assumes that 100% of those who have received two doses of vaccine will get a third dose at 6 months.

**Figure 23.1.** The estimated inpatient hospital usage is shown over time. The percent of hospital beds occupied by COVID-19 patients is color-coded based on observed quantiles of the maximum proportion of beds occupied by COVID-19 patients. Less than 5% is considered *low stress*, 5-9% is considered *moderate stress*, 10-19% is considered *high stress*, and 20% or greater is considered *extreme stress*.
Figure 24.1. The estimated intensive care unit (ICU) usage is shown over time. The percent of ICU beds occupied by COVID-19 patients is color-coded based on observed quantiles of the maximum proportion of ICU beds occupied by COVID-19 patients. Less than 10% is considered low stress, 10-29% is considered moderate stress, 30-59% is considered high stress, and 60% or greater is considered extreme stress.
More information

Data sources:
Mask use and vaccine confidence data are from the The Delphi Group at Carnegie Mellon University and University of Maryland COVID-19 Trends and Impact Surveys, in partnership with Facebook. Mask use data are also from Premise, the Kaiser Family Foundation, and the YouGov COVID-19 Behaviour Tracker survey.
Genetic sequence and metadata are primarily from the GISAID Initiative. Further details available on the COVID-19 model FAQ page.

A note of thanks:
We wish to warmly acknowledge the support of these and others who have made our COVID-19 estimation efforts possible.
