COVID-19 Results Briefing

European Union

December 22, 2021

This document contains summary information on the latest projections from the IHME model on COVID-19 in the European Union. The model was run on December 21, 2021, with data through December 13, 2021.

In this release, we have substantially revised our model to reflect the emergence of the Omicron variant, waning infection-acquired and vaccine-acquired immunity, and the matrix of immunity across variants. Our reference scenario suggests that over the next two months, more than 60% of the EU population will likely be infected with Omicron. Because of a much greater fraction of asymptomatic infections (likely over 90%), and thus a lower infection-detection rate, we expect diagnosed cases will increase to a peak of 1.4 million by the end of January 2022. Based on the data from South Africa, the United Kingdom, Denmark, and Norway, we expect that the infection-hospitalization rate (IHR) for Omicron compared to Delta will be 90%–96% lower. Despite the lower IHR, the pressure on hospitals is likely to be considerable in some member states. The EU peak hospital census will likely be similar to the peak last winter. Likewise, based on the available data, we expect the infection-fatality rate (IFR) will be 97%–99% lower than for Delta. Huge numbers of infections and moderate numbers of hospitalizations may still translate into a peak of reported daily deaths under 4,000 by early February.

Our forecasts are more optimistic than some forecasts, such as those from the SAGE group in the United Kingdom, which has put out numbers suggesting massively higher daily deaths than at any prior point in time. While we believe our reference forecast reflects the available evidence on Omicron, huge uncertainties remain for key assumptions: Omicron immune escape, increased transmissibility, substantial reduced vaccine-specific efficacy for preventing infection, moderate reductions in vaccine-specific efficacy in preventing hospitalization and death, the speed of waning vaccine-derived immunity for infection and hospitalization/death, the speed of waning of infection-acquired immunity, and severity of Omicron infection. The most important uncertainty is how severe Omicron infection is. Our assumptions on reduced severity may turn out to be pessimistic; for example, hospital admissions in the UK are rising extremely slowly. In our more severe Omicron scenario, hospital census could reach levels above 175,000 and reported daily deaths could be near 5,000.

Decision-makers need to choose courses of action in the face of very considerable uncertainty. We expect holiday period lags in reporting cases, hospitalizations, and deaths will heighten uncertainty until early January. Sufficient data to revise our assessment of severity may not emerge until the second or third week of January.
What policy responses are available? We have included in this release scenarios of increasing mask use to 80%, increasing third-dose vaccine delivery from 80% in the reference scenario to 100% of those who received 2 doses, and making progress against vaccine hesitancy. Given the speed of global spread of Omicron and the very short doubling time for Omicron transmission, increasing mask use to 80% has the most immediate and largest impact. Our third dose scenario has a small effect because of two assumptions: third doses are only delivered 6 months after the second dose, and the reference scenario already has 80% receiving the third dose. In future releases, we will test the impact of shorter intervals for the third dose such as 3-4 months. While not explicitly modeled, given the transmissibility of Omicron, promoting the use of higher-quality masks such as KN95 or N95 would be consistent with the available data. Given the rapid spread and much reduced IHR and IFR, we do not believe elementary or secondary school closures are appropriate. More aggressive lockdowns to control transmission may reduce the pressure on some hospital systems but will come at considerable economic and social cost. Given that screening programs are likely to yield many asymptomatic cases, workplace screening and protocols on how long individuals need to stay away from work may need to be modified – otherwise there may be a considerable impact on some employers and on some supply chains. Extremely high rates of transmission and reported cases may also mean that contact tracing may be ineffective and potentially a waste of resources. With high infection rates and the projected stress on some hospitals, hospitalization rates should be used as a metric to drive policy at the local level. The medical system is already exhausted, and some medical staff may get infected and have to isolate, so the workforce may be impacted even more. There are huge variations in the capacity of hospitals to expand to meet the surge and local metrics are needed.

Individuals can act to protect themselves by getting vaccinated if not already vaccinated and getting a third does as soon as they are eligible. Individuals at any elevated risk due to age or comorbidities who wish to reduce their risk of hospitalization or death should wear a mask, preferably a high-quality mask such as an N95 mask, and avoid situations where transmission is more likely, such as any indoor gathering or outdoor gathering where distancing is not possible. Individuals who are not vaccinated or have never been infected should also be particularly concerned.

Current situation

- Daily infections in the last week increased to 1,106,000 per day on average compared to 775,700 the week before (Figure 1.1).

- Daily hospital census in the last week (through December 13) increased to 32,700 per day on average compared to 30,000 the week before.

- Daily reported cases in the last week increased to 244,000 per day on average compared to 224,400 the week before (Figure 2.1).

- Reported deaths due to COVID-19 in the last week were constant at 1,700 per day on average compared to 1,700 the week before (Figure 3.1).
Total deaths due to COVID-19 in the last week were constant at 2,500 per day on average compared to the week before (Figure 3.1). This makes COVID-19 the number 2 cause of death in the European Union this week (Table 1). Estimated total daily deaths due to COVID-19 in the past week were 1.4 times larger than the reported number of deaths.

The daily rate of reported deaths due to COVID-19 is greater than 4 per million in 12 countries and 7 subnational locations (Figure 4.1).

The daily rate of reported deaths due to COVID-19 is greater than 4 per million in 17 countries and 15 subnational locations (Figure 4.2).

We estimate that 33% of people in the European Union have been infected at least once as of December 13 (Figure 6.1).

Effective R, computed using cases, hospitalizations, and deaths, is greater than 1 in the majority of the EU (Figure 7.1). Notable exceptions are some countries in the eastern and southeastern parts of the EU.

The infection-detection rate in the European Union was close to 41% on December 13 (Figure 8.1).

Based on the GISAID and various national databases, combined with our variant spread model, we estimate the current prevalence of variants of concern (Figures 9.1–9.5). We estimate that the Alpha variant is circulating in 0 member states and 0 subnational locations, that the Beta variant is circulating in 0 member states and 0 subnational locations, that the Delta variant is circulating in 23 member states and 56 subnational locations, that the Gamma variant is circulating in 0 member states and 0 subnational locations, and that the Omicron variant is circulating in 23 member states and 56 subnational locations.

**Trends in drivers of transmission**

- Mask mandates remain in place in all but 5 countries. Denmark has introduced new business curfews. Further mandates have been introduced this week that are not reflected in this table.

- Mobility last week was 9% lower than the pre-COVID-19 baseline (Figure 11.1), reflecting a downward trend since September. Mobility was lower than 30% of baseline in Austria (Figure 12.1).

- As of December 13, in the COVID-19 Trends and Impact Survey, 57% of people self-report that they always wore a mask when leaving their home, reflecting a steady increase since early November (Figure 13.1).

- There were 732 diagnostic tests per 100,000 people on December 13 (Figure 15.1).

- As of December 13, 12 member states and 50 subnational locations have reached 70% or more of the population who have received at least one vaccine dose, and 9 countries and 36 subnational locations have reached 70% or more of the population who are fully vaccinated (Figure 17.1). 72% of people in the European Union have received at least one vaccine dose and 67% are fully vaccinated.
In the European Union, 85.9% of the population that is 12 years and older say they would accept or would probably accept a vaccine for COVID-19. Note that vaccine acceptance is calculated using survey data from the 18+ population. The proportion of the population who are open to receiving a COVID-19 vaccine ranges from 47% in Bulgaria to 100% in Malta and the Netherlands (Figure 19.1).

In our current reference scenario, we expect that 323.0 million people will be vaccinated with at least one dose by April 1 (Figure 20.1). We expect that 69% of the population will be fully vaccinated by April 1.

**Projections**

**Infections**

- Daily estimated infections in the **reference scenario**, which represents what we think is most likely to happen, will rise to 4.5 million by January 19, 2022 (Figure 21.1).

- Daily estimated infections in the **high severity of Omicron scenario** will rise to 4.6 million by January 19, 2022 (Figure 21.1).

- Daily estimated infections in the **80% mask coverage scenario** will rise to 3.3 million by January 19, 2022 (Figure 21.1).

- Daily estimated infections in the **third dose scenario** will rise to 4.1 million by January 19, 2022 (Figure 21.1).

- Daily estimated infections in the **reduced vaccine hesitancy scenario** will rise to 4.5 million by January 19, 2022 (Figure 21.1).

**Cases**

- Daily cases in the **reference scenario** will rise to 1.4 million by January 30, 2022 (Figure 21.2).

- Daily cases in the **high severity of Omicron scenario** will rise to 1.4 million by January 30, 2022 (Figure 21.2).

- Daily cases in the **80% mask coverage scenario** will rise to 1.0 million by January 30, 2022 (Figure 21.2).

- Daily cases in the **third dose scenario** will rise to 1.3 million by January 30, 2022 (Figure 21.2).

- Daily cases in the **reduced vaccine hesitancy scenario** will rise to 1.4 million by January 30, 2022 (Figure 21.2).

**Hospitalizations**

- Daily hospital census in the **reference scenario** will rise to 124,000 by February 11, 2022 (Figure 21.3).
• Daily hospital census in the **high severity of Omicron scenario** will rise to 184,000 by February 12, 2022 (Figure 21.3).

• Daily hospital census in the **80% mask coverage scenario** will rise to 105,000 by February 10, 2022 (Figure 21.3).

• Daily hospital census in the **third dose scenario** will rise to 115,000 by February 10, 2022 (Figure 21.3).

• Daily hospital census in the **reduced vaccine hesitancy scenario** will rise to 122,000 by February 11, 2022 (Figure 21.3).

**Deaths**

• In our **reference scenario**, our model projects 1,152,000 cumulative reported deaths due to COVID-19 on April 1. This represents 279,000 additional deaths from December 13 to April 1. Daily reported COVID-19 deaths in the **reference scenario** will rise to 3,890 by February 2, 2022 (Figure 21.4).

• Under our **reference scenario**, our model projects 1,650,000 cumulative total deaths due to COVID-19 on April 1. This represents 408,000 additional deaths from December 13 to April 1 (Figure 24.2).

• In our **high severity of Omicron scenario**, our model projects 1,222,000 cumulative reported deaths due to COVID-19 on April 1. This represents 349,000 additional deaths from December 13 to April 1. Daily reported COVID-19 deaths in the **high severity of Omicron scenario** will rise to 4,910 by February 7, 2022 (Figure 21.4).

• In our **80% mask coverage scenario**, our model projects 1,103,000 cumulative reported deaths due to COVID-19 on April 1. This represents 231,000 additional deaths from December 13 to April 1. Daily reported COVID-19 deaths in the **80% mask coverage scenario** will rise to 3,260 by January 16, 2022 (Figure 21.4).

• In our **third dose scenario**, our model projects 1,110,000 cumulative reported deaths due to COVID-19 on April 1. This represents 239,000 additional deaths from December 13 to April 1. Daily reported COVID-19 deaths in the **third dose scenario** will rise to 3,160 by January 31, 2022 (Figure 21.4).

• In our **reduced vaccine hesitancy scenario**, our model projects 1,146,000 cumulative reported deaths due to COVID-19 on April 1. This represents 274,000 additional deaths from December 13 to April 1. Daily reported COVID-19 deaths in the **reduced vaccine hesitancy scenario** will rise to 3,810 by February 2, 2022 (Figure 21.4).

• Figure 22.1 compares our reference scenario forecasts to other publicly archived models. Forecasts are widely divergent.

• At some point from December through April 1, one member state will have high or extreme stress on hospital beds (Figure 23.1). At some point from December through April 1, 13 member states will have high or extreme stress on intensive care unit (ICU) capacity (Figure 24.1).
Model updates

In this update, we have substantially revised our model to explicitly account for several important factors that have a profound influence on the likely trajectory of the epidemic in the coming months. First, the model tracks infections from different variants separately, including ancestral, Alpha, Beta, Gamma, Delta, Omicron, and other. Second, we take into account that infection-derived and vaccine-derived immunity wanes over time. Immunity that prevents infection wanes more quickly than immunity preventing hospitalization and death, so we derive separate waning curves for infection and for hospitalization and death. Based on a systematic analysis of published studies, reports, and archived studies, we derive vaccine-specific waning curves. Third, infection with different COVID-19 variants can confer different protection for each variant in the model. The matrix of cross-variant immunity allows us to take into account the greater immune escape seen with Omicron. Third, we explicitly model the delivery of a third dose of vaccine (and second dose for J&J recipients). Fourth, the variant spread model is now based on both spatial spread and patterns of airline traffic. The technical appendix provides details of the model structure and the analysis of waning immunity. The critical driver of our forecasts in the next months is the spread of the Omicron variant. Critical assumptions about the Omicron variant are based on our analysis of all the available lab data on vaccine efficacy, test-negative vaccine effectiveness studies in South Africa and the UK, population-level data on PCR positivity in representative samples of the population, and detected cases, hospitalization, and deaths in South Africa, the UK, Denmark, and Norway. More details on this analysis are in the technical appendix. The key assumptions that substantially influence the forecasts include the following: First, prior infection provides 40% to 60% protection against infection with Omicron. Second, vaccine effectiveness in preventing infection is reduced by approximately 50% compared to the efficacy against the Delta variant, and vaccine effectiveness in preventing hospitalization and death is reduced by 25% compared to the efficacy against the Delta variant. Third, the fraction asymptomatic is assumed to increase from near 40% to 90%–95%; this fraction influences the future estimates of the infection-detection rate. Fourth, the infection-hospitalization rate for Omicron is estimated to be 90%–96% lower than for Delta variant. Fifth, the infection-fatality rate for Omicron is estimated to be 97%–99% lower than for Delta.

Figure 7.1. Mean effective R on December 2, 2021. Effective R less than 1 means that transmission should decline, all other things being held the same. The estimate of effective R is based on the combined analysis of deaths, case reporting, and hospitalizations where available. Current reported cases reflect infections 11-13 days prior, so estimates of effective R can only be made for the recent past.
Figure 8.1. Percent of estimated COVID-19 infections detected. This is estimated as the ratio of reported daily COVID-19 cases to estimated daily COVID-19 infections based on the SEIR disease transmission model. Due to measurement errors in cases and testing rates, the infection-detection rate can exceed 100% at particular points in time.

Figure 20.1. Percent of people who receive at least one dose of a COVID-19 vaccine and those who are fully vaccinated.
Projections and scenarios

We produce five scenarios when projecting COVID-19. The reference scenario is our forecast of what we think is most likely to happen:

- Vaccines are distributed at the expected pace. Brand- and variant-specific vaccine efficacy is updated using the latest available information from peer-reviewed publications and other reports.
- Future mask use is the mean of mask use over the last 7 days.
- Mobility increases as vaccine coverage increases.
- Omicron variant spreads according to our flight and local spread model.
- 80% of those who have had two doses of vaccine (or one dose for Johnson & Johnson) receive a third dose at 6 months after their second dose.

The high severity of Omicron scenario modifies the reference scenario assumption in two ways: * The infection-hospitalization ratio for Omicron is 2.3 times as high as compared to the reference scenario. * The infection-fatality rate is 4.6 times as high as compared to the reference scenario.

The 80% mask use scenario makes all the same assumptions as the reference scenario but assumes all locations reach 80% mask use within 7 days. If a location currently has higher than 80% use, mask use remains at the current level.

The third dose scenario is the same as the reference scenario but assumes that 100% of those who have received two doses of vaccine will get a third dose at 6 months.

The reduced vaccine hesitancy scenario assumes that those in each location who respond on surveys that they probably will not receive a vaccine are persuaded or mandated to receive a vaccine.

Daily deaths

covid19.healthdata.org Institute for Health Metrics and Evaluation
Figure 22.1. Comparison of reference model projections with other COVID modeling groups. For this comparison, we are including projections of daily COVID-19 deaths from other modeling groups when available, last model update in brackets: Delphi from the Massachusetts Institute of Technology (Delphi) [December 21, 2021], Imperial College London (Imperial) [December 5, 2021], the SI-KJalpha model from the University of Southern California (SIKJalpha) [December 19, 2021], and the ECDC Ensemble Model (ECDC) [December 20, 2021]. Daily deaths from other modeling groups are smoothed to remove inconsistencies with rounding. Regional values are aggregates from available locations in that region.
Figure 23.1. The estimated inpatient hospital usage is shown over time. The percent of hospital beds occupied by COVID-19 patients is color-coded based on observed quantiles of the maximum proportion of beds occupied by COVID-19 patients. Less than 5% is considered low stress, 5-9% is considered moderate stress, 10-19% is considered high stress, and 20% or greater is considered extreme stress.
Figure 24.1. The estimated intensive care unit (ICU) usage is shown over time. The percent of ICU beds occupied by COVID-19 patients is color-coded based on observed quantiles of the maximum proportion of ICU beds occupied by COVID-19 patients. Less than 10% is considered low stress, 10-29% is considered moderate stress, 30-59% is considered high stress, and 60% or greater is considered extreme stress.
More information

Data sources:

Mask use and vaccine confidence data are from the The Delphi Group at Carnegie Mellon University and University of Maryland COVID-19 Trends and Impact Surveys, in partnership with Facebook. Mask use data are also from Premise, the Kaiser Family Foundation, and the YouGov COVID-19 Behaviour Tracker survey.

Genetic sequence and metadata are primarily from the GISAID Initiative. Further details available on the COVID-19 model FAQ page.

A note of thanks:

We wish to warmly acknowledge the support of these and others who have made our COVID-19 estimation efforts possible.
