

COVID-19 Results Briefing

United States of America

July 18, 2022

This document contains summary information on the latest projections from the IHME model on COVID-19 in United States of America. The model was run on July 15, 2022, with data through July 13, 2022.

The BA.5 Omicron subvariant in the US has been associated with a modest increase in cases and deaths and a larger increase in hospital admissions. In other countries, such as South Africa, the BA.5 wave lasted from start to peak about 4–5 weeks and was associated with a minimal increase in deaths. Across nations in Europe and Latin America, many different patterns have emerged with very different increases in cases, hospitalizations, and deaths. The heterogeneity of response is likely related to different levels of home testing that is not reported in official data, along with inclusion in many – but not all – countries of hospitalizations with deaths with COVID-19 but not due to COVID-19. Despite 2 ½ years of the pandemic, our current ability to make sense of the pandemic has declined as data systems have become less, not more, comparable during the Omicron period.

Although it is harder to make sense of some of the trends, it is likely given the experience in other countries that the BA.5 surge will be relatively short-lived in the order of 4–6 weeks. Nor do we expect a major increase in deaths due to COVID-19 given high levels of past exposure to COVID-19, either through past infection or through vaccination. We estimate that only 2% of those who are not vaccinated still want to be vaccinated, so that expanding new vaccinations is unlikely to be a major control strategy. The main strategies available are: 1) encouraging second boosters more widely to counteract declining immunity in those who have not been recently infected; 2) broad use of Paxlovid in those at risk of severe disease; 3) selective use of social distancing and mask wearing in individuals at risk due to age or comorbidities. The most important short- to medium-term strategy is to maintain and improve surveillance. Given the confusing signal in reported cases, hospital admissions, and deaths, the government should require reporting hospitalizations and deaths where COVID-19 is the underlying cause of admission or death separated from incidental admissions and deaths where patients are COVID-19 positive but have other conditions leading to hospitalization or death.

Current situation

- Estimated daily infections in the last week remained approximately constant at 851,000 per day on average compared to 884,000 the week before (Figure 1.1).
- Daily hospital census in the last week (through July 13) increased to 40,000 per day on average compared to 37,000 the week before.
- Daily reported cases in the last week increased to 112,000 per day on average compared to 108,000 the week before (Figure 2.1).

- Reported deaths due to COVID-19 in the last week increased to 360 per day on average compared to 350 the week before (Figure 3.1).
- Total deaths due to COVID-19 in the last week increased to 460 per day on average compared to 440 the week before (Figure 3.1). This makes COVID-19 the number five cause of death in US this week (Table 1). Estimated total daily deaths due to COVID-19 in the past week were 1.3 times larger than the reported number of deaths.
- The daily rate of reported deaths due to COVID-19 is greater than 4 per million in no states nor the District of Columbia (Figure 4.1).
- The daily rate of total deaths due to COVID-19 is greater than 4 per million in two states (Figure 4.2).
- We estimate that 82% of people in US have been infected at least once as of July 11 (Figure 6.1).
- Effective R, computed using cases, hospitalizations, and deaths, is greater than 1 in 34 states and the District of Columbia (Figure 7.1).
- Based on the GISAID and various national databases, combined with our variant spread model, we estimate the current prevalence of variants of concern (Figures 9.1–9.5). The dominant variant in all states is Omicron with subvariants BA.5 increasing in prevalence.

Trends in drivers of transmission

- Mobility last week was 6% lower than the pre-COVID-19 baseline (Figure 11.1). Mobility was lower than 15% of baseline in three states (Figure 12.1).
- As of June 24, in the COVID-19 Trends and Impact Survey, 16% of people self-reported that they always wore a mask when leaving their home (Figure 13.1).
- There were 204 diagnostic tests per 100,000 people on July 11 (Figure 15.1).
- As of July 11, 33 states and the District of Columbia have reached 70% or more of the population who have received at least one vaccine dose, and 22 states and the District of Columbia have reached 70% or more of the population who are fully vaccinated (Figures 17.1 and 17.2). 80% of people in US have received at least one vaccine dose, and 69% are fully vaccinated.
- As of June 24, 2022, two percent of the population in US say they would accept a vaccine for COVID-19 but have not yet been vaccinated.
- In our current reference scenario, we expect that 261.3 million people will be vaccinated with at least one dose by November 1 (Figure 19.1). We expect that 74% of the population will be fully vaccinated by November 1.

Projections and scenarios

We produce three scenarios when projecting COVID-19. The **reference scenario** is our forecast of what we think is most likely to happen:

- Vaccines are distributed at the expected pace. Brand- and variant-specific vaccine efficacy is updated using the latest available information from peer-reviewed publications and other reports.
- Future mask use will decline to 50% of the minimum level it reached between January 1, 2021, and May 1, 2022. This decline begins after the last observed data point in each location and transitions linearly to the minimum over a period of six weeks.
- Mobility increases as vaccine coverage increases.
- 80% of those who are fully vaccinated (two doses for most vaccines, or one dose for Johnson & Johnson) receive an additional dose six months after becoming fully vaccinated, and 80% of those who receive an additional dose receive a second additional dose six months later.
- Antiviral utilization for COVID-19 risk prevention has reached 80% in high-risk populations and 50% in low-risk populations between March 1, 2022, and June 1, 2022. This applies in high-income countries, but not low- and middle-income countries, and this rollout assumption follows a similar pattern to global vaccine rollouts.

The **80% mask use scenario** makes all the same assumptions as the reference scenario but assumes all locations reach 80% mask use within seven days. If a location currently has higher than 80% use, mask use remains at the current level.

The **antiviral access scenario** makes all the same assumptions as the reference scenario but assumes globally distributed antivirals and extends coverage to all low- and middle-income countries between August 15, 2022, and September 15, 2022.

Infections

- Daily estimated infections in the **reference scenario** will decline to 254,770 by September 19, 2022 (Figure 21.1).
- Daily estimated infections in the **80% mask use scenario** will decline to 24,400 by October 2, 2022 (Figure 21.1).
- Daily estimated infections in the **antiviral access scenario** will decline to 254,770 by September 19, 2022 (Figure 21.1).

Cases

- Daily estimated cases in the **reference scenario** will rise to 115,560 by July 16, 2022 (Figure 21.2).
- Daily estimated cases in the **80% mask use scenario** will rise to 114,100 by July 15, 2022 (Figure 21.2).

- Daily estimated cases in the **antiviral access scenario** will rise to 115,560 by July 16, 2022 (Figure 21.2).

Hospitalizations

- Daily hospital census in the **reference scenario** will rise to 42,400 by July 13, 2022 (Figure 21.3). At some point from July through November 1, one state will have high or extreme stress on hospital beds (Figure 23.1). At some point from July through November 1, no states will have high or extreme stress on intensive care unit (ICU) capacity (Figure 24.1).
- Daily hospital census in the **80% mask use scenario** will rise to 42,260 by July 13, 2022 (Figure 21.3).
- Daily hospital census in the **antiviral access scenario** will rise to 42,400 by July 13, 2022 (Figure 21.3).

Deaths

- In our **reference scenario**, our model projects 1,047,000 cumulative reported deaths due to COVID-19 on November 1. This represents 30,000 additional deaths from July 11 to November 1. Daily reported COVID-19 deaths in the **reference scenario** will rise to 470 by July 31, 2022 (Figure 21.4).
- Under our **reference scenario**, our model projects 1,332,000 cumulative total deaths due to COVID-19 on November 1. This represents 39,000 additional deaths from July 11 to November 1 (Figure 21.5).
- In our **80% mask use scenario**, our model projects 1,034,000 cumulative reported deaths due to COVID-19 on November 1. This represents 17,000 additional deaths from July 11 to November 1. Daily reported COVID-19 deaths in the **80% mask use scenario** will rise to 460 by July 30, 2022 (Figure 21.4).
- In our **antiviral access scenario**, our model projects 1,047,000 cumulative reported deaths due to COVID-19 on November 1. This represents 30,000 additional deaths from July 11 to November 1. Daily reported COVID-19 deaths in the **antiviral access scenario** will rise to 470 by July 31, 2022 (Figure 21.4).
- Figure 22.1 compares our reference scenario forecasts to other publicly archived models. Forecasts are widely divergent.

Model updates

This month, we have made two alterations to our reference scenario assumptions and one alteration to our antiviral scenario assumptions in the model. First, in the reference scenario, we included an estimate for an additional vaccination dose (second booster). As was previously done with the first booster, we assumed 80% of those who are fully vaccinated (two doses for most vaccines, or one dose for Johnson & Johnson), receive an additional dose six months after becoming fully vaccinated. In this model, we assume 80% of those who receive an additional dose (first booster) receive a second additional dose (second booster) 4-6 months later. Distribution assumptions were time-corrected based on reported data. We estimated each vaccination course using the doses administered in the previous course, taking into account the number of doses available based on manufacturer distribution data. We updated this process to estimate supply and demand on a daily basis rather than periodically.

Second, we expect the recent rollout of Paxlovid treatments in high-income settings to greatly reduce severe disease and death outcomes. We only currently have data from the United States to inform levels of antiviral coverage and have used these data to update our scale-up model from last month. The model assumes individuals in high-income countries had been targeted for treatment, and access to treatment among this group had risen from 0% on March 15, 2022, to a maximum of 80% for high-risk individuals and 50% for low-risk individuals by June 1, 2022. This rollout assumption follows a similar pattern to global vaccine rollouts. [Clinical trials](#) suggest that Paxlovid provides an 88% reduction in the risk of hospitalization and death among people treated within five days of symptom onset. We made an additional assumption that if roughly 70% of deaths and 50% of admissions are incidental (defined as patients who test positive for COVID after being admitted to the hospital for other reasons), Paxlovid effectiveness among patients admitted primarily for COVID treatment would be 25-30% for deaths and 40-50% for admissions.

Lastly, we have made one alteration to our antiviral scenario assumptions in the model. Our scale-up model assumes that global distribution of antivirals will extend to all low- and middle-income countries between August 15, 2022, and September 15, 2022. Similar to the reference scenario, we assume a linear scale-up to a maximum of 80% access for high-risk individuals and 50% for low-risk individuals during this time frame.

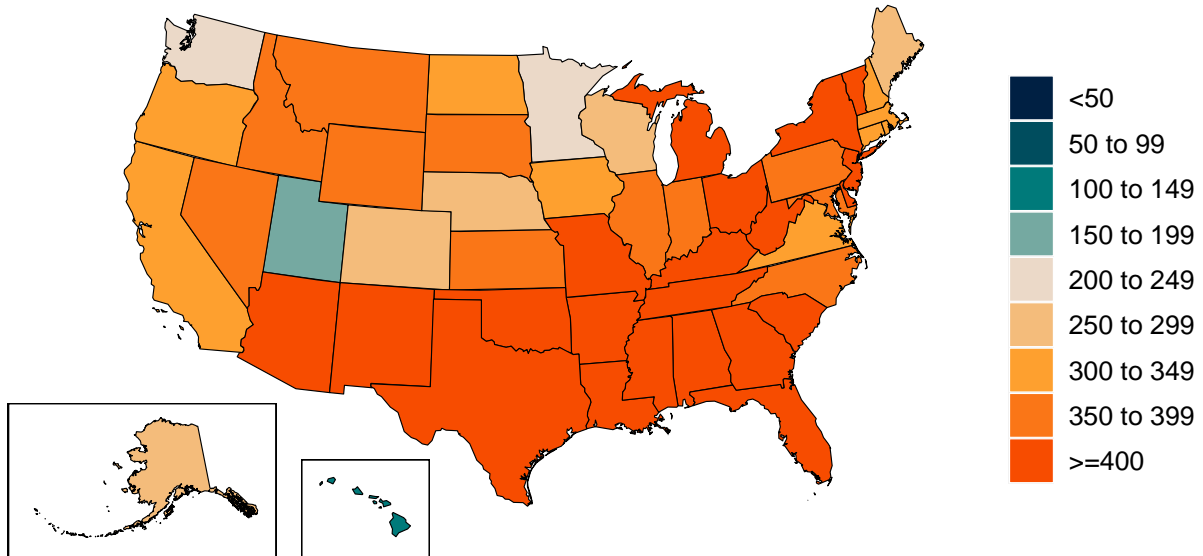

Figure 6.1: Estimated percent of the population infected with COVID-19 on July 11, 2022

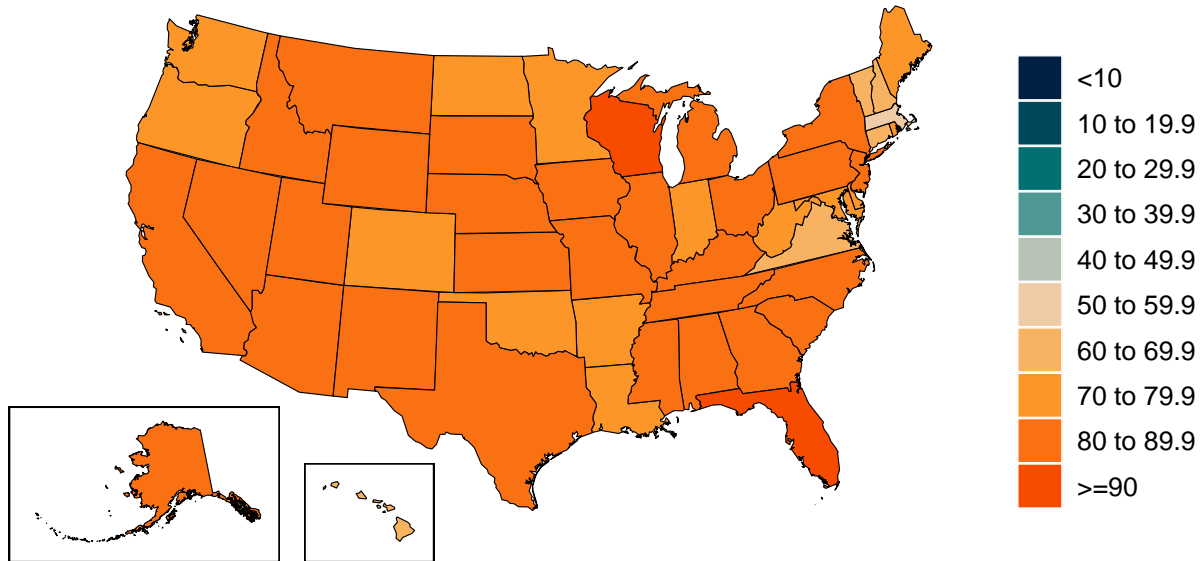

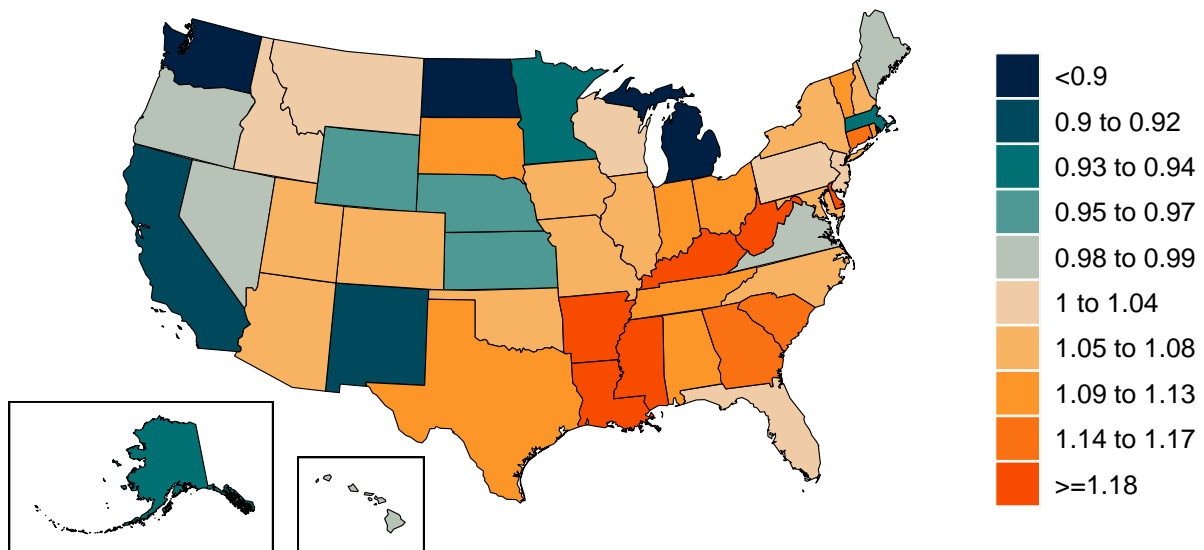

Figure 7.1: Mean effective R on June 30, 2022. Effective R less than 1 means that transmission should decline, all other things being held the same. The estimate of effective R is based on the combined analysis of deaths, case reporting, and hospitalizations where available. Current reported cases reflect infections 11-13 days prior, so estimates of effective R can only be made for the recent past.
